Euler[1] also obtained a constant value for *k*, using a clear esterase prepared from pig's adipose tissue and ethyl butyrate. As he gives only one experiment and did not vary the concentration of the butyrate, it is impossible to say that the monomolecular law is obeyed.

Turning now to the reaction in heterogeneous solution, we will consider first the lipase from the castor oil bean (*Ricinus communis*). Armstrong and Ormerod[2] have shown that a slightly acid medium is necessary for the action of this enzyme, but that variations of 2500 per cent. in added acetic acid and of 500 per cent. in added citric acid make practically no difference in its hydrolysis of castor oil. Although this lipase has unfortunately been obtained only in insoluble form it should on account of its behavior towards acids be of great value for kinetic work. Animal lipases act best in a nearly neutral medium and apparently do not act on such a wide variety of esters as the ricinus lipase. The nature of the two lipases therefore may be fundamentally different. A. E. Taylor[3] in his work on this ferment found that in one instance it showed complete agreement with the monomolecular law. Working under rather difficult experimental conditions, he found that the values of *k* agreed very closely when triacetin was used as zymolyte. The extreme variation in each series was about 25 per cent., but for three different concentrations of ester, 0.5 per cent., 1 per cent. and 2 per cent., the mean values of *k* agreed very closely. When, however, he used ethyl acetate he found that *k* was about twice as great in the 2 per cent. as in the 1 per cent. solution. The result with triacetin is, of course, of the greatest importance. The result with ethyl acetate is practically unique, as in all other cases of enzyme action that are comparable with this *k* is greater in the weaker concentrations of the zymolyte. I cannot, however, pretend to have consulted more than a small part of the literature.

Very interesting and significant results have also been obtained by Bodenstein and Dietz,[4] using a turbid pancreatic extract and amyl butyrate They followed the reaction in both directions and obtained good agreement with the *mono*- and *bi*-molecular laws as long as they did not vary the initial concentration of their zymolyte. When this was varied, however, they, too, found that k likewise varied in inverse proportion.

A great variety of other results have been obtained but the few researches given above are typical of the more careful work done during the past ten years. The investigators who consider that they have confirmed Schütz's rule (to be considered in the next paragraph) have for the most part worked with heterogeneous systems of at least three phases. This makes their work extremely difficult to interpret. It is noteworthy that practically everyone who has worked with the simpler solutions considers that Schütz's rule is, in the case of lipase at least, untenable, and that the amount of enzyme action is proportional to the mass of the enzyme. These results are scattered through the literature but some experimental evidence for the statement will be given later.

It may not be out of place in this connection to consider Schutz's rule. It may be given as follows: With a given reaction volume and a given initial concentration of zymolyte the amount of reaction products are proportional to the product of the square root of the enzyme mass and the square root of the time. Expressed in a formula this may be written $x = k\sqrt{Et}$ where x = the amount of reaction products, k = a constant for the stated volume and zymolyte concentration, E = the enzyme mass and t = the time.

Generally speaking, we cannot consider it improbable that the zymolyte and its reaction products will influence the activity of the enzyme and will do so differently in their different concentrations. Therefore it is better to compare the strength of the enzyme in two different solutions by the time taken to attain to a given stage of the reaction. In this way we shall eliminate as far as possible the different activity of the enzyme in different conditions of the medium. Working on this principle we can measure the activity of the enzyme by the reciprocal of the time taken to produce a given quantity of reaction products. (The reaction volume and initial zymolyte concentration are, of course, supposed to be constant.) For instance, if in one reaction mixture it takes twice as long to produce a given amount of acid as in another reaction mixture, we may say that the first reaction mixture has twice the enzymic activity of the second. We may formulate this by saying that Enzymic activity = k/t or Enzymic activity $\times\ t = k$; where k is a constant for given initial conditions (with exception of enzymic mass) and given amount of reaction products. This is a general rule in the nature of a definition, and therefore independent of all experimental evidence.

If, however, in addition, we find that the enzymic activity as determined in this way is proportional to the enzymic mass, we will have a most valuable experimental rule. We may formulate it $Et = k$, where E = the enzyme mass (an experimentally given quantity). As we have stated, this rule is of the greatest empirical value besides having abundant theoretical justification. Schütz's rule, on the other hand, requires a rather elaborate theoretical calculation to justify its existence and as the experimental work becomes more carefully planned is seen to have less and less empirical value.

Thus as a summary of the above researches we may say that the lipolytic reaction has frequently been shown to follow the monomolecular law so long as only one initial concentration of zymolyte was employed. In only one case (triacetin and ricinus lipase) was k shown to be the same with different concentrations of zymolyte. In another case k and the initial concentration of the zymolyte were directly proportional to each other. In all other cases k was larger in the weaker zymolyte concentrations, in some cases being inversely proportional to the concentration. The amount of enzymic action as measured by the reciprocal of the time to attain a given stage of the reaction was proportional to the mass of enzyme present.

In my investigation I have used a carefully dried and twice redistilled ethyl butyrate and the lipase prepared from pig's liver. The enzyme solution was prepared as follows: Small pieces of freshly killed pig's liver were dissected free from vessels and connective tissue and rinsed off with distilled water. These pieces were then ground with sand and water and strained through cloth. The extract obtained from 50 cc. of liver was made up to 500 cc. and the resulting solution called "10 per cent." extract. After several days' standing under toluene at room temperature this was filtered through paper and a clear, highly refractive, deep straw-colored liquid obtained. It was again filtered after two and again after nine months. The filtrate was now much lighter than formerly, though still quite active, and was much more suitable for use with indicators. A small portion of this solution was mixed with 500 cc. of an ethyl butyrate solution previously warmed to 37° and the mixture kept at this temperature The time of the beginning of the reaction (which was not more than 3 seconds in error) was taken as the time when one-half of the enzyme had flowed into the ethyl butyrate solution from a pipette. At suitable intervals 50 cc. of this solution was removed with a pipette, allowed to flow onto snow in a beaker and immediately titrated with 0.05 N NaOH free from carbonate, phenolphthalein being used as an indicator. The time of completion of the reaction was taken when one-half of the solution had gone onto the snow. The error in the measurement of t was probably not more than 6 seconds and the error in the measurement of x not more than 0.10 cc. though generally less than 0.5 cc. In all cases the acidity of the extract used has been deducted from the observed figures, so that the figures given are all corrected ones. For each 50 cc. of reaction mixture the initial acidity was 0.82 cc. 0.05 N

NaOH in the 0.476 per cent. solution, 0.34 cc. in the 0.196 per cent. solution and 0.17 cc. in the 0.099 per cent. solution.

The largest error is undoubtedly the temperature error. The temperature of the bath was within 0.1° of 37° during practically the entire reaction, but occasionally varied 0.2–0.4° for a few minutes. As the temperature coefficient of the reaction is about 10 per cent. for each degree, this introduces a slight factor of uncertainty, but it was not possible under my limitations of time to secure a better regulation, nor would the results to have been attained have warranted it. All experiments were done in duplicate, except the experiment in the 4th column in Table VII. As it differs slightly from the others, however, I did not feel justified in excluding it absolutely.

After considerable preliminary work in perfecting the technique, my first experiment showed that the reaction velocity fell off gradually from the beginning of the reaction.

39.54	487.5	0.002301
39.43	488.0	0.002269

This falling off was supposed to be due to the accumulation of acid in the system, in accordance with the explanation proposed by Kastle, Johnston and Elvove. To test this hypothesis further, I used a much more dilute solution of enzyme (0.099 per cent.), so that the reaction would be better followed, and also used six different strengths of zymolyte.

---

These figures are obtained by interpolation and occasional extrapolation from Table II. The function changes slowly for any given series and the calculation therefore is generally not difficult. Whenever the observed figures show a maximum or minimum I have used that maximum or minimum value for the nearest corresponding value of x, as it would probably lie nearer the true value than a figure obtained by interpolation. The six cases where this occurs are marked in the table by an asterisk (*).

I naturally expected that "k" would be the same in each concentration or very nearly so and that it would show a falling off from the beginning to the end of the reaction. Instead of this it was, roughly speaking, inversely proportional to the concentration of the ester.[1] Further, the function $1/t \log [a/(a - x)]$, though falling off markedly in the two stronger solutions, fell off only slightly in the "$a = 21.40$" solution, and even increased in the other three.

If we tabulate the time taken to split a definite amount of ethyl butyrate, the apparent law becomes clearly evident. We find that this time is practically independent of the concentration of the butyrate itself, whereas by the mass law it should bear an inverse relation to it. The time taken to split up a given amount of ethyl butyrate first shows perceptible increase when the concentration of the ester falls below $N/200$ (*i. e.*, 5.00 cc. of 0.05 N NaOH per 50 cc.). These times are given in Table III. The figures are obtained by calculating backward from the values of $1/t \log [a/(a - x)]$ given in Table II*a*.

TABLE III.

Time in minutes to produce x cc. of acid.

Enzyme — 0.090%

x	$a = 43.53$	$a = 32.56$	$a = 21.40$	$a = 10.62$	$a = 5.66$	$a = 2.74$.

The table is divided into three parts by two broken lines. To the left of the heavy line where the ester concentrations is above $N/200$, the figures on each horizontal line are nearly the same (*i. e.*, within 8 per cent. of each other). To the right of the dotted line they are con-

---

[1] This statement is true only for the values corresponding to $x = 1.00$ but anyone who cares to do so can see that it is also nearly true for other values of x, if the expression

$$\frac{1}{t_2 - t_1} \log \frac{a - x_1}{a - x_2}$$

is used. Table III can be used as a basis for this calculation.

siderably larger. Between the heavy and the dotted lines they are only slightly larger (10–15 per cent.) than the figures to the left of the heavy line.

It will be noticed that it took longer to produce 10 cc. of acid in the $a = 43.53$ solution than in the $a = 32.56$ or $a = 21.40$ solutions. Whether much importance should be attributed to this fact I cannot say. It seems to be a greater difference than can be accounted for by experimental errors.

The facts brought out in Table III can be shown even more plainly if instead of the time taken to produce x cc. of acid we tabulate the time taken to produce 1 cc. of acid at different stages of the reaction. Thus the time taken to produce the first cc. of acid in the three stronger solutions is 8.78, 8.85 and 8.84 minutes, respectively, while the time taken to produce the second cc. is 10.90, 10.69 and 10.43 minutes.

TABLE IV.

Time in minutes to produce 1 cc. of acid in different acid concentrations.

Concentration of acid	Enzyme = 0.099 per cent.					
	$a = 43.53$	$a = 32.56$	$a = 21.40$	$a = 10.62$	$a = 5.06$	$a = 2.74$
$x = 0.00–1.00$	8.78	8.85	8.84	9.16	10.62	11.61
$x = 1.00–2.00$	10.90	10.69	10.43	10.91	12.75	17.11
$x = 2.00–3.00$	12.62	11.86	11.60	11.75	15.53	....
$x = 3.00–4.00$	13.50	14.03	12.39	13.35	20.55	
$x = 4.00–5.00$	14.83	14.06	13.20	13.85	38.55	...
$x = 5.00–6.00$	14.61	14.78	13.83	16.76	.	.....
$x = 6.00–7.00$	16.71*	15.65	14.84*	20.30	..	.....
$x = 7.00–8.00$	17.73	16.56	16.32	25.90	.....	.....
$x = 8.00–9.00$	17.96	17.31	17.22	42.76	....	.....
$x = 9.00–10.00$	19.76	19.24	18.70	85.05	.....	....

* These two asterisks note the largest deviation to the left of the heavy line.

Here we notice the important fact that the time taken to produce 1 cc. of acid depends mainly on the reaction of the medium and very little on the concentration of the ethyl butyrate. That is, as long as the concentration of the ester is above $N/200$ it takes practically the same time to produce 1 cc. of acid in a mixture of given acidity. Although above this limit the concentration of the ester makes very little difference, yet when it falls below this limit the time taken to produce 1 cc. of acid increases rapidly. This is seen very well by comparing the 3rd and 4th series in the above table. In contrast to this comparative independence of the ester concentrations, the reaction of the medium is of the greatest importance. For instance, in the three stronger solutions it takes about twice as long to produce the ninth cc. of acid as the first cc. In the $a = 21.40$ solution the ester concentration has by this time fallen to about five-eighths its original value. It therefore makes little difference in this one case whether we attribute this increase in time to the diminished ester concentration or the increased acidity. In the two stronger solutions, however, the ester concentration has fallen only to $^3/_4$ and $^4/_5$ of its initial value and we should therefore expect it to take only $^4/_3$ and $^5/_4$ as long to produce the ninth cc. of acid as the first. Instead we find that in these two solutions, as well, the time is approximately doubled. If we assume that the reaction would have followed the monomolecular law, but that the activity of the enzyme is decreased by the acidity of the solution, we see from Table II*a* that it is diminished in different amounts in these three solutions, and is actually increased in the $a = 10.62$ solution.

We see, therefore, from this series of experiments, that on its face, at least, the reaction does not follow the monomolecular law. Even when only one reaction at a time is considered, the explanation required is complicated, while when the six series are considered together the difficulties become almost insuperable. The amount of material reacting per instant is not proportional to the amount of material present at that instant, even when due allowance is made for acidity. On the other hand, provided only that the acidity is the same in the two solutions to be compared, the amount of ester reacting per instant is practically independent of the ester concentration over considerable wide limits ($N/23$–$N/200$).

We may indeed well question whether the constancy of the function $1/t \log [a/(a - x)]$ for the two series $a = 10.62$ and $a = 21.40$ is not purely accidental.

The question then arises: how are we to explain this apparent deviation from the mass law? The answer is, I think, very simple. We may assume that the action takes place in two stages with the formation of an intermediate compound. The first stage is a reaction between the enzyme and the zymolyte (here the ethyl butyrate) with the formation of this hypothetical intermediate compound; the second stage is the splitting up of this intermediate substance into free enzyme, alcohol and acid. At what stage of the reaction the water enters into this series of changes is not important for the following discussion, but we can represent the possibilities in two ways.

In the first equation the water does not enter into the formation of the intermediate compound, while it does in the second equation.

$$\text{Ester} + \text{Enzyme} + \text{Water} \rightleftarrows \left(\begin{smallmatrix}\text{Ester}\\ \text{Enzyme}\end{smallmatrix}\right) + \text{Water} \rightleftarrows \text{Alcohol} + \text{Acid} + \text{Enzyme}$$

or

$$\text{Ester} + \text{Enzyme} + \text{Water} \rightleftarrows \left(\begin{smallmatrix}\text{Ester}\\ \text{Enzyme}\\ \text{Water}\end{smallmatrix}\right) \rightleftarrows \text{Alcohol} + \text{Acid} + \text{Enzyme}.$$

By the mass law, the amount of acid production (which is what we measure) would be proportional to the concentration of this intermediate compound. If then our reaction constants bear such a proportion to each other that in ester concentrations from $N/23$ to $N/200$ most of the enzyme is held in such a compound, we can easily see that the amount of hydrolysis would be practically independent of our ester concentration.

With a little further consideration we can even make an approximate calculation of the percentage of enzyme present in the free and combined states. In the first place the amount of enzyme is so small that the total quantity present must react several times per second, and hence the system can never be very far from equilibrium so far as the enzyme itself is concerned. This being so, we have:

$$(\text{Concentration free enzyme})^m \times (\text{Concentration ester})^n = k_1\,(\text{Conc. intermediate compound})^p$$

where m, n and p represent the number of molecules of the substances entering into the reaction.

We have, however, absolutely no data for assigning values to m, n and p and hence can simplify the equation by making them equal to 1, that is by assuming that one molecule of enzyme reacts with one molecule of ester to form one molecule of the intermediate compound.

We have then:

$$\text{Conc. free enzyme} \times \text{Conc. ester} = k_1\ \text{Conc. int. compd.} \qquad (1)$$

and since the amount of acid produced per instant (or per small unit of time[1]) is proportional to the concentration of our intermediate compound we have:

$$k_2\ \text{Conc. int. compd.} = \text{acid produced per minute} \qquad (2)$$

from which we can obtain by division a third equation:

$$\text{Conc. free enz.} \times \text{Conc. ester} = k_1/k_2\ \text{acid produced per minute.} \qquad (3)$$

Using these equations as a basis for calculation I obtained the figures in the following table (Table V). The mean amount of ester present during the production of the first cc. of acid is the acid equivalent of the ester present at the beginning of the reaction minus 0.5 cc The rate of acid production is also a mean value, being merely the reciprocal of the time taken to produce the first cc. of acid.

TABLE V

	Enzyme = 0.009%.					
	a = 43.53.	a = 32.56	a = 21.40	a = 10.62.	a = 5.66	a = 2.74.
Mean concentration of ester during production of 1st cc. of acid	43.0	32.1	20.9	10.1	5.16	2.24
Minutes taken to produce 1 cc. of acid	8.78	8.85	8.84	9.16	10.62	11.61
cc. of acid produced per minute	0.114	0.113	0.113	0.109	0.094	0.086
Free enzyme (per cent. of total enzyme)	1.7	2.3	3.7	7	12	25
Combined enzyme (per cent. of total enzyme)	98.3	97.7	96.3	93	88	75

---

[1] To avoid the difficulties of the differential notation, I have generally used a small but finite time and quantity unit (1 minute and 1 cc.). The error is, I think, very small.

The figures in the last two lines are obtained by successive approximations and it would not be of especial interest to give these at length. Instead I give a table which shows that they coincide very nearly with the observations.

TABLE VI.

	Enzyme = 0.099%.					
	$a = 43.53$	$a = 32.56$.	$a = 21.40$.	$a = 10.62$	$a = 5.66$	$a = 2.74$.
$\frac{\text{Acid produced per minute}}{\text{\% free enzyme} \times \text{mean amt of ester}}$	0.0153	0.0153	0.0150	0.0154	0.0152	0.0154
$\frac{\text{Acid produced per minute}}{\text{Per cent. combined enzyme}}$	0.0116	0.0116	0.0118	0.0117	0.0107	0.0115

The agreement is thus seen to be very good except in the series $a = 5.66$. It was in this series that the calculation of the time taken to produce 1 cc. met with a little difficulty and here the discrepancy may be only an apparent one.

I wish to emphasize that the above calculation is to be regarded as purely hypothetical and only adopted for the purpose of giving a mechanism by which the reaction may be conformed to the mass law. The argument, of course, loses its validity if we do not assume the presence of an intermediate compound, but merely because the results obtained by a highly hypothetical calculation correspond fairly closely with the observations, we must not therefore conclude that an intermediate compound is necessarily present.

It is tacitly assumed in the above argument that the amount of enzyme action is proportional to the amount of enzyme present. This has been shown repeatedly, but it is so essential to my argument that I feel it necessary to give my own observations. We have seen that it is advisable to measure the enzymic activity by the reciprocal of the time taken to produce a given amount of acid, and formulated this as $E = k/t$ or $Et = k$, where $E =$ the enzymic mass in a given volume or the enzymic concentration.

The following table summarizes my results with three different strengths of enzyme and various ester concentrations.

TABLE VII.

Time in minutes to produce x cc. in acid.

	Enzyme = 0.476%.	Enzyme = 0.196%			Enzyme = 0.099%.

* Concentration of ester is below $N/200$.

Leaving out of consideration the figures marked with an asterisk (*) and considering the figures marked with a dagger (†) as only approximate, we see that Et is very nearly a constant for any given concentration of acid, although the enzyme is slightly more active in the 0.476 per cent. series. Practically every investigator who has done carefully planned work with lipase in one or two phase solutions has also concluded that the enzyme activity is proportional to the enzymic concentration.

The main thesis of this paper is that the amount of zymolyte hydrolyzed per instant is independent of the concentration of the zymolyte over a considerable range. This has been shown to be true for invertase by A. Brown,[1] Hudson[2] and Taylor,[3] for diastase by Taylor[3] and for lipase by Kastle and Loevenhart[4] and by Kastle, Johnston and Elvove.[5] Brown also gave a partial explanation of the phenomenon somewhat similar to the one I have given. The peculiarities in the hydrolyses of the ester and cane sugar are due to the enzyme and not to the substances hydrolyzed, since when acids are used as catalytic agents the progress of the action conforms absolutely to the mass law. This has been shown by numerous investigators beginning with Wilhelmy[6] in the case of cane sugar in 1857. Ostwald,[7] among others, has investigated the kinetics of both actions very completely and Cohen[8] has shown that the cause of the apparent deviation of the acid inversion of cane sugar from the monomolecular law is due to the volume of the solution occupied by the sugar. Morse and his co-workers have shown that the osmotic pressure of cane sugar is equal to the gas pressure of a gas occupying the volume of water present in the sugar solution under consideration. Therefore, if in the expression $k = 1/t \log [a/(a - x)]$, we make a and x proportional to the osmotic pressure, instead of to the concentration of the sugar, we will have a very close agreement of k in the different concentrations. The osmotic pressure of the zymolyte cannot be invoked to explain the anomalies which I have noted in the above cases of enzyme action, as the variations of k are in the wrong direction. On the other hand the explanation which I have given or some modification of it, can be invoked to explain the anomalies of the action of invertase and diastase.

It may be of interest in this connection to give the results of other investigators bearing on the above statements.

(1) A. Brown.[1]

INVERTASE ACTING ON CANE SUGAR.

	Grams sugar per 100 cc	Grams sugar inverted in 60 min	$1/t \log [a/(a - x)]$.
A	40 02	1.076	
	29 96	1.235	
	19 91	1.335	
	9 85	1.335	
	4 89	1.230	
B.	(2 0)	(0.308)	(0.00132)
	1 0	0.249	0.00219
	0.5	0 129	0 00239
	0.25	0.060	0.00228

Apparently two different enzyme solutions were used. The monomolecular law is followed only in dilute solutions. In the stronger solutions the absolute amount inverted in 60 min. is nearly independent of the sugar concentration. In the three most dilute solutions k is nearly the same but is much smaller in the 2 per cent. solution than in the 1 per cent. solution. Though not calculated for the stronger solutions, it would, of course, be about inversely proportional to the concentration of the sugar.

(2) Hudson.[2]

INVERTASE ACTING ON CANE SUGAR.

Cane sugar per 100 cc.	Grams inverted in 30 minutes per 100 cc. solution.	Grams inverted in 60 minutes per 100 cc solution.
4.55	3.33	4.23[3]
9.09	4.12	6.74
27.3	3.06	6.00

(3) Kastle and Loevenhart.[4]

[1] Brown, *J. Chem. Soc.*, 81, 373 (1902), tables on 379 and 387.

[2] Hudson, THIS JOURNAL, 30, 1575 (table).

[3] The concentration of cane sugar was only 1.22 per cent. at the beginning of the second 30 minutes of the reaction.

[4] Kastle and Loevenhart, *Am. Chem. J.*, 24, 514; cf. Kastle, Johnston and Elvove, *Loc. cit.*, 31, 546.

LIPASE ACTING ON ETHYL ACETATE.

Grams ethyl acetate per 5 cc.	Grams ethyl acetate hydrolyzed in 15 minutes per 5 cc. solution.
0.05656	0.003952
0.04242	0.003861
0.02828	0 003952
0.01414	0.003403

The agreement in the three stronger solutions is remarkable.

(4) Taylor[1] gives interesting figures for invertase and diastase. He gives only the reaction constants. These multiplied by the per cent. of the zymolyte show close agreement in the stronger solutions.

INVERTASE ON CANE SUGAR.

Per cent. sugar.	$k \times 10^4$.	$(k \times 10^4) \times$ per cent. sugar.
½	423	212
1	326	326
2	167	334

DIASTASE ON MALTOSE.

Per cent. maltose	$k \times 10^6$.	$(k \times 10^6) \times$ per cent. maltose.
1	363	363
2	239	478
3	142	426

The enzyme action in these three cases is thus seen to differ markedly from the hydrolysis by acids.

Conclusions.

(1) In a solution of given volume and acidity the time taken to hydrolyze a given amount of ethyl butyrate is inversely proportional to the concentration of the enzyme. Under similar conditions of acidity each particle of enzyme hydrolyzes the same absolute amount of ester per instant no matter what the concentration of enzyme.

(2) With a given concentration of enzyme the time taken to hydrolyze a given amount of ethyl butyrate is dependent on the acid concentration but independent of the ester concentration, provided this is above $N/200$. In other words for each concentration of acid a given amount of enzyme hydrolyzes very nearly the same amount of ethyl butyrate over a wide range of ester concentration.

(3) This phenomenon can be conformed to the mass law by assuming that the enzyme and the ester form an intermediate compound, which in concentrations of the ester above $N/200$ contains most of the enzyme.

(4) Assuming that the amount of this intermediate compound at any instant is proportional to the product of the concentration of the free enzyme and the ester, we saw that the rate of acid production was proportional to this quantity. This hypothesis, therefore, is seen to be in perfect accordance with the mass law.

(5) No explanation is offered as to the inhibiting effect of the acid.

(6) The question is raised as to whether the constancy of the function $1/t \log [a/(a-x)]$ in certain cases is not purely accidental.

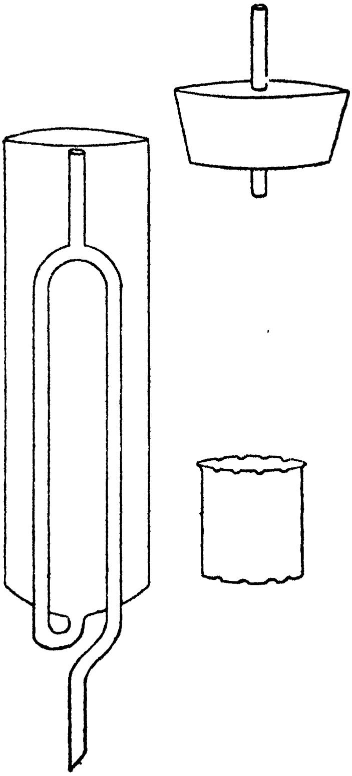
NOTE.

Extraction Apparatus.—For the extraction of a substance by means of a mixture of solvents (*e. g.*, 50 per cent. alcohol), distillation and the use of a reflux condenser being inadmissible, I have devised a form of apparatus shown in the accompanying diagram. It consists of a glass tube 4 × 12 cm. terminating at the bottom in an outside siphon tube $9^{1}/_{2}$ cm. long, the upper bend of which has a short open "riser" fitted with a short piece of rubber tubing. A support for the extraction cartridge may be made by cutting off a section about 3 cm. long from the open end of a wide test-tube and indenting its edges.



This support having been inserted, the extraction cartridge with contents is introduced and then the mixed solvent. After standing a sufficient time, the solvent is drained off by clamping the rubber tube attached to the "riser," closing the large tube with a stopper bearing an open glass tube, and forcing air through the latter. The large tube having been drained, the solvent in the extraction cartridge is allowed to drain into the space below it and the siphon again started. In this way, *all* of the solvent can be removed before the second portion is introduced.

Advantages.—(1) There is no stopcock (as in separatory funnels) which may leak or require contaminating grease under the penalty of possible sticking. (2) The siphon action, being under control, makes possible the complete draining of the apparatus between successive extractions and also prevents the undesirable premature draining of the apparatus such as sometimes occurs when the siphon tube becomes filled with a broken column of liquid or when too much solvent is unintentionally introduced and the siphon action thereby started. (3) The apparatus can be stoppered easily and evaporation, with subsequent variation in the proportion of the solvents, prevented.

NEW BOOKS.

Leitfaden für den Unterricht in der anorganischen Chemie didaktisch bearbeitet. VON DR. JOACHIM SPERBER. Dritter Teil. Zurich, Verlag von E. Speidel, 1910. 536 pages.

The first part of this general treatise on inorganic chemistry appeared in 1899 and was reviewed by Prof. Henry Fay in THIS JOURNAL, **22,** 222. The second part appeared in 1901 and was reviewed by Prof. Fay in THIS JOURNAL, **24,** 197. The present volume bears the date 1910 and constitutes the third and final volume of the work.

The first two volumes dealt primarily with the non-metals and general theories of chemistry. The third volume is essentially a discussion of the metals and their compounds. About forty pages at the beginning of the volume are devoted to the halogen and sulphur compounds of the non-metals and a few pages at the end to the periodic law and the author's theory of valence. The periodic classification is adhered to in the order of the discussion of the metals. The treatment is clear and comprehensive and the volume is deserving the same general approval as was given to the earlier volumes by Prof. Fay. In the "Schlussbemerkung" the author states that because of the increased cost in publication some of the illustrations as well as table of contents had to be omitted. The omission of an index from such a publication needs no comment.

WILLIAM MCPHERSON.

Physical Chemistry for the Electrical Engineers. By J. LIVINGSTON R. MORGAN. John Wiley & Sons, 1909. Second edition, revised. $1.50.

It is becoming necessary to offer courses in electrochemistry to electrical engineering students but a considerable knowledge of physical chemistry is a necessary preliminary and as these students are generally lacking in this, Professor Morgan's little book is a welcome supplementary text. The first six chapters (184 pages) are devoted to the properties of gases, solutions, chemical mechanics, equilibrium in electrolytes, etc. The author has followed Ostwald's idea and avoided as much as possible the use of hypotheses and has succeeded in presenting these things concisely but still in an interesting way. Some have questioned the advisability of neglecting our ideas of atoms and molecules since the student is already familiar with this point of view from his beginning chemistry and will come across it in his future contact with things chemical. The objection has some weight; on the other hand the presentation is sufficiently different from what the student might have expected to arouse his interest and attention and this is essential, as otherwise little or nothing is thought out or retained. The essential principles of electrochemistry proper are briefly presented. A more frequent mention of the application of these principles to things which are familiar to the electrical engineer would

add much to the book, particularly should some of the problems be from this standpoint.
G. A. HULETT.

Principles of Chemical Geology. By JAMES VINCENT ELSDEN. London and New York: Whittaker & Co., 1910. pp. vi+220. Cloth.

The title of this book is somewhat misleading, for it is not a general treatise on chemical geology. It is really and professedly an attempt to apply the theory of equilibrium to geological problems, and therefore it covers a well-defined but limited field. The specific questions to which modern physico-chemical ideas and principles are applicable are discussed with some detail in an elementary way, with abundant illustrations of their applicability and a wealth of references to literature. Such themes as viscosity, diffusion, surface tension, vapor pressure, eutectics and solid solutions are considered, and their bearing upon the magma and its solidification are clearly treated. The work of men like LeChatelier, Arrhenius, Doelter, Vogt, Ostwald, van't Hoff and Morozewicz is fully discussed, that of van't Hoff upon the Stassfurt salts being given considerable prominence. English and American workers are also extensively cited, showing that the author has gone quite thoroughly over the available literature. There are, here and there, minor errors in purely chemical and mineralogical matters, but they are so few that they do not lessen the value of the book to any serious extent. The volume will certainly be most helpful to many progressive geologists, for magmatic problems are coming more and more into the field of physical chemistry. What happens when molten rock solidifies, or when a bed of rock salt or gypsum is deposited from solution? Questions like these must be handled by modern methods, and the philosophical geologist can no longer be content with the chemistry of thirty years ago.
F. W. CLARKE.

Beiträge zu einer Kolloidchemie des Lebens. VON RAPHAEL ED. LIESEGANG. Dresden: Verlag von Theodor Steinkopff, 1909. 148 pp. Price, 4 mks.

This is a collection of heterogeneous experiments dealing with the formation of precipitation membranes of various phosphates, silver chloride, copper ferrocyanide, etc., in gelatin, which are supposed to, and possibly do in some particulars, parallel the processes of formation of membranes, growth, partial permeability, and resorption, occurring in living cells.

The experiments are not planned apparently with any definite end in view nor is any explanation given of some of the results. An idea of the scope of the experiments, of which there are one to several included under each heading, may be obtained from a partial list of the chapter headings of Part 1, pp. 1–77. "Apparent membrane effects; the passage of circles of diffusion through each other; speed of diffusion; the apparent attraction of diffusion circles; rhythmic after-diffusion; carbon dioxide development in gelatin; apposition and intersusception; the acid theory of osteomalacia; the growth of hollow bones; rachitis; calcium phosphate membranes; pressure effects; bone archetectonics; hydrogen peroxide and gelatin; researches on nucleic acid." The second part of 78 pages contains more protocols with suggestions of their possible bearing on bone formation, muscle contraction, conduction, etc.

It is sufficient to give a list of the chapter headings and the number of pages to show the necessarily superficial, incomplete and incoördinate character of the work. Almost any one of the titles mentioned would require for any adequate treatment a book of at least the size of this one. The book can not be recommended as an example of what a scientific work should be, but rather, in the reviewer's opinion, as an excellent example of what it should not be. There are no fundamental guiding principles for the experiments, there is no thorough working out of any one thing to see whether the experiments reported really parallel vital phenomena except in a grossly superficial way. Even the title of the book, "Contributions to a Colloidal Chemistry of Life," strikes the reviewer as badly chosen to say the least, since in the first place, life is not to be explained by chemistry even taken as a whole, let alone that part of it dealing with the colloids, and in the second place it is still uncertain that colloids differ in any fundamental particular from noncolloids, so that a separate division of chemistry for them would appear certainly premature. It is possible that the author's industry in trying experiments of precipitation in gelatin, may enable some one to find among the experiments some stones which may be used in erecting a planned building, or he may find here some hints in shaping further work which may be useful but apart from this, the work has little value owing to its incoördinate and inconclusive character.

Any one who feels tempted to publish work of this kind should read any one of Darwin's books, or any book or paper of Claude Bernard, Lavoisier, Faraday, DuBois Raymond, van't Hoff, or any of the great men of science to get a standard of excellence. He will not find that these men publish hodge-podges of this kind, which, alas, are altogether too common in all branches of biological investigation.

STUDIES IN VAPOR PRESSURE, VI: A QUANTITATIVE STUDY OF THE CONSTITUTION OF CALOMEL VAPOR.

BY ALEXANDER SMITH AND ALAN W. C. MENZIES.

Received October 15, 1910.

Numerous determinations of the vapor density of calomel at atmospheric pressure have shown, within the limits of error of the methods, that the density corresponds to the formula HgCl. Odling[1] was the first to show, by the amalgamation of a gold-leaf dipped in the vapor, that free mercury was present. The vapor was, therefore, at least partly composed of a mixture of $Hg + HgCl_2$, in equimolecular proportions, which would have the same density as HgCl. Debray[2] could find no amalgamation at 400°, but Brereton Baker[3] obtained it at 445°. Erlenmeyer[4] condensed the vapor rapidly on a tube filled with cold mercury, but found less than 0 03 g. of free mercury in the large deposit of sublimed calomel. Debray secured a similar result with a gilded, silver U-tube containing running water. The presence of free mercury was therefore established, but the evidence, so far as it went, demonstrated only a small amount of dissociation.

Harris and V. Meyer,[5] after confirming by a number of determinations the value of the vapor density previously accepted, attempted in two ways to ascertain the amount of dissociation. In the first place, by heating calomel at about 465° in a porous vessel enclosed in a wider glass tube, they secured, by diffusion, a "dense mass" of free mercury in the cold part of the outer tube and a "considerable amount" of corrosive sublimate in the residue remaining in the porcelain cell. They infer that this proves "copious dissociation" in calomel vapor. It is obvious, however, that a very small degree of dissociation in the vapor would account for this result equally well. The exit of the mercury through the pores would be expected to disturb a state of equilibrium between the undissociated calomel and the dissociation products, and to result in the final liberation of a far larger proportion of mercury than that contained in the original vapor. This experiment, and another of a similar nature, therefore, in reality only confirmed Odling's proof that some free mercury was present, without in the least degree indicating its amount. The question whether the proportion of undecomposed HgCl in the vapor was over 90 per cent. or zero remained unanswered.

The experiment just described being of a physical nature, Harris and Meyer sought confirmation by chemical means of the (unwarranted) conclusion they had drawn from it. They assume that a vapor largely composed of HgCl should give the reactions of a mercurous salt, while one composed largely of Hg and $HgCl_2$ should give the reactions of a mercuric salt. A rod coated with solid caustic potash, and preheated in an empty test tube (240–260°), was quickly immersed in the vapor of calomel contained in another tube at the same temperature. A yellowish red layer of mercuric oxide appeared immediately. The authors recognize the fact that mercurous oxide is unstable at this temperature, but seem to think it would necessarily have been formed *as a transient stage* if HgCl had been present. They smeared a similar rod with mercurous oxide and, preheating being out of the question, dipped it, cold, into the calomel vapor. After a "long (*geraumer*) time—15–25 seconds," the color changed to yellow owing to the decomposition of the oxide into Hg + HgO. The conclusion drawn from these two experiments is that, since not even a trace of transient darkening was observed with the potash, the mercuric oxide could not have arisen from previously formed mercurous oxide, but must have been the direct product of interaction with the calomel vapor. This mild inference is doubtless correct. But the following clause, stating that the vapor therefore contains the combined mercury as mercuric chloride, indicates complete confusion of thought. Since mercurous oxide is unstable at 240–260°, why should its formation be counted upon under any circumstances at this temperature? True, metastable substances are sometimes produced, but more often they are not. In this case, certainly, the deposition of mercuric oxide would be quite as natural with a vapor wholly composed of a mercurous compound as with one wholly composed of a mercuric salt.

On an experimental foundation which, to say the least, is thus eminently inconclusive, the authors base their final statement: "In vaporizing, calomel decomposes completely according to the equation $Hg_2Cl_2 = Hg + HgCl_2$." This conclusion, that no HgCl is contained in the vapor, by reason of the confidence with which it is stated, has been very generally accepted, and is the view universally held by chemists. Since it was published, no further investigation of the matter seems to have been made. The controversy with Fileti[1] which arose out of this paper, added nothing regarding the possibility of the presence of calomel, as such, in the vapor. It did draw from V. Meyer the statement that he had "never made the mistake of holding that *his experiments* with calomel furnished proof of the double formula," but we are not here concerned with the left-hand side of the equation quoted above. It afforded, also, additional proofs that V. Meyer did not fully understand the principles of chemical equilibrium involved in the problem he had undertaken to solve.

The important fact discovered since V. Meyer's work is that noted by Brereton Baker (*l. c.*), namely, that, in the vapor of *carefully dried* calomel, a gold leaf is not amalgamated. If this observation could be accepted as proving the entire absence of free mercury from the vapor, it would demonstrate conclusively the presence of HgCl, at least in the vapor of the dried substance. This inference follows from the fact that the density of Hg_2Cl_2 is 16 26 (air = 1), while the mean of Baker's measurements with dried calomel is only 15. Thus, if there was no dissociation into $Hg + HgCl_2$, two molecules in every 13 (or 15 4 per cent. of the total molecules) were HgCl. We have seen, however, that the gold-leaf test is uncertain, and it would therefore be unsafe to draw any such conclusion.

An examination of the literature thus reveals the fact that, at the present time, no experimental data exist on which can be based an inference, or even a guess, in regard to the proportion of dissociated ($Hg + HgCl$) to undissociated (HgCl) molecules in calomel vapor.

Theory of the Method Used to Solve the Problem.—The inconclusiveness of the previous investigations is due chiefly to two facts, namely, that the problem is a quantitative one, while the experiments directed to its solution were all qualitative, and that the experiments and the reasoning applied to the observations were ill considered. If we assume for the present that a polymolecular form of calomel (say Hg_2Cl_2) is present in the vapor only in negligible amounts, or is absent entirely, as the vapor density determinations seem to show, then there are at most three substances present in the vapor, namely HgCl, Hg, and $HgCl_2$. Their relations in the *saturated* vapor, when solid calomel is in equilibrium with the gases, is shown by the following scheme of equilibria:

---

[1] Fileti, *Gazz. chim. ital.*, 11, 341 (1881), *J. prakt. Chem.*, [2] 50, 222; 51, 197. V Meyer, *Ber.*, 27, 3143; 28, 364

$$\text{Calomel (solid)} \rightleftarrows 2\text{HgCl (vapor)} \rightleftarrows \text{Hg} + \text{HgCl}_2.$$

There are three unknown quantities, namely the partial pressures of HgCl, of Hg, and of $HgCl_2$. Three independent observations are required, theoretically, for the measurement of the values of these three quantities at a given temperature. The three observations which appeared to be most suitable were:

1. The vapor pressure of calomel, P_{calom}. This gives the total value of the three partial pressures.

2. The joint vapor pressure of a mixture of calomel and mercury, with both substances in excess, $P_{\text{mixt.}}$.

3. The vapor pressure of mercury alone, $P_{\text{merc.}}$.

The results of these three measurements are related in such a way that, with the help of the fundamental laws of chemical equilibrium, the three partial pressures may be calculated from them. It is more convenient, however, to handle the resulting data in another way, namely, by considering first the two extreme cases.

If we first assume the proportion of free mercury in calomel vapor to be exceedingly small, and the dissociation therefore to be negligible, then the vapor of calomel is essentially composed of HgCl, and the relation between the observed data is simple. Each single substance (Exps. 1 and 3), at a fixed temperature, gives a fixed vapor pressure. The concentration of the vapor, which determins the vapor pressure, cannot be permanently altered so long as the solid, or liquid, phase is present. In the mixture (Exp. 2), if the liquid mercury and the solid calomel are immiscible, as they appear to be (see, however, below), and if there is no chemical interaction between their vapors (and there is none), and if the vapors have no component in common (a condition fulfilled in that absence of dissociation which we are for the moment assuming), then the vapor pressure of the mixture must be sensibly equal to the sum of the vapor pressures of mercury and of calomel as measured separately at the same temperature, that is:

$$P_{\text{mixt.}} = P_{\text{merc}} + P_{\text{calom.}}. \qquad (1)$$

If, on the other hand, we assume that the dissociation is complete, then HgCl is absent from the vapor: Calomel (solid) $\rightleftarrows$ Hg + $HgCl_2$, and the vapor pressure of calomel (Exp. 1) is made up of only two partial pressures:

$$P_{\text{calom.}} = p_{\text{merc.}} + p_{\text{corros.}}.$$

In this instance, with the mixture (Exp. 2) the mercury and the calomel both furnish mercury vapor, but the fact that the latter is also giving off mercury does not cause a permanent increase in the total concentration of mercury vapor beyond that which mercury by itself can give. The partial pressure of mercury vapor in the mixture is fixed by the presence of the free, liquid mercury at a value identical with the vapor pressure of mercury in the absence of calomel at the same temperature. Hence:

$$P_{\text{mixt}} = P_{\text{merc.}} + p'_{\text{corros.}} \qquad (2)$$

Here the partial pressure of corrosive sublimate in the mixed vapors is determind by the chemical equilibrium between the dissociation products of calomel. Now with pure calomel:

$$p_{\text{merc.}} = p_{\text{corros.}} = \tfrac{1}{2} P_{\text{calom.}}$$

and the value of the calomel dissociation constant is:

$$p_{\text{merc}} \times p_{\text{corros.}} = \text{const.} = (\tfrac{1}{2} P_{\text{calom.}})^2.$$

In the mixture, the constant, and therefore the product of the partial pressures, must have the same value, so that:

$$P_{\text{merc.}} \times p'_{\text{corros.}} = (\tfrac{1}{2} P_{\text{calom.}})^2$$

and

$$p'_{\text{corros.}} = (\tfrac{1}{2} P_{\text{calom.}})^2 \div P_{\text{merc.}}.$$

Hence, substituting in equation 2, the vapor pressure of the mixture is:

$$P_{\text{mixt}} = P_{\text{merc}} + \frac{(\tfrac{1}{2} P_{\text{calom.}})^2}{P_{\text{merc.}}}. \qquad (3)$$

Thus the vapor pressure of the mixture can be calculated (equation 1 for no dissociation, equation 3 for complete dissociation) from the vapor pressures of calomel and mercury measured separately, and can also be observed directly. If either of these extreme cases represents the facts, then the agreement of the calculated with the observed data will show which assumption is correct.

It will be noted that the assumption that the dissociation is negligible gives the greatest value for the total pressure for the mixture. The assumption that the dissociation is complete gives the minimum value for the same total pressure. If HgCl is present, a value between these two will be found. In case intermediate values are obtained, then the partial pressure (p_{calom}) of undecomposed calomel, HgCl, can be calculated from the relation:

$$p_{\text{calom.}} = P_{\text{calom}} - 2\left[P_{\text{merc.}} \pm \sqrt{(P_{\text{mixt}} - P_{\text{calom.}})\, P_{\text{merc.}}}\right], \qquad (4)$$

of which equation 3 is the particular case when $p_{\text{calom.}} = 0$.

At the time, about ten years ago, when this mode of solving the problem first presented itself to one of us, no suitable and simple method of measuring vapor pressures was known, and a higher degree of accuracy was required than any of the known methods seemed to possess at the vaporizing point of calomel. Methods involving confinement over mercury were excluded, because the value of the vapor pressure of calomel in the absence of mercury was required. Ramsay and Young's dynamic method was not sufficiently accurate, as their results with a dissociating solid of similar volatility—ammonium chloride[1]—showed. The spiral gage alone seemed applicable, but the difficulties connected with its use were deterrent. It was with the object of finding simple methods, applicable to solids and to difficult cases, and at the same time accurate enough to be employed in quantitative chemical work, and therefore suitable for the solution of the calomel problem, that the whole study of methods of determining vapor pressures was undertaken. These methods have already been described. Of the three vapor pressures, a knowledge of which was required, only that of mercury had been measured. But the data given by different observers were so discordant that a redetermination of even these values[2] was necessary.

The Vapor Pressures of Calomel.—The vapor pressures of calomel[3] were determined with the static isoteniscope, using the mixture of potassium and sodium nitrates as the confining fluid, as well as in the bath. The isoteniscope, platinum resistance thermometer, and the other parts of the apparatus, and the manipulation, and the corrections and precautions employed, were all identical with those described in connection with the work on water[4] and used again in the work on mercury (*l. c.*). The slow interaction with the nitrates of the mercuric chloride in the vapor results in the gradual production of a slight precipitate of mercuric oxide. But the presence of this precipitate in no way interferes with the use of the liquid as a confining fluid. On the other hand, the resulting accumulation of a slight excess of mercury in the vapor, since it occurs at a point remote from the calomel in the bulb, does no harm. Diffusion of this mercury back into the bulb and its penetration to the surface of the calomel would be required in order that it might disturb the equilibrium and affect the vapor pressure. The excess of mercury is formed so slowly, and the diffusion of mercury vapor is in itself so very slow, that prolonged waiting would be required for the development of any effect. Hence, even if the method did not provide, as it does provide, for the complete expulsion of all the accumulated vapor, and its replacement by a fresh supply, immediately before each reading, no slow increase in pressure would arise from this cause. In point of fact, none was ever observed.

The dynamic isoteniscope[5] would have been selected, instead of the static one, but for the fact that to secure strictly comparable results it was desirable to employ static methods for all three determinations.

[5] This series, No. 5, THIS JOURNAL, 32, 1448 (1910).

Had the interaction with the nitrates been more rapid, or the vapor more swiftly diffusible, the use of the dynamic form of apparatus would have been necessary for exactness.

The observed vapor pressures are reduced to mm. of mercury at 0° and the sea level at 45° latitude. The temperatures are on the thermodynamic scale, assuming the sulphur boiling point as 445°:

t	*p*	*t.*	*p.*
361.82	454.7	388.11	866.7
371.07	563.7	403.79	1229.7
380.41	724.6		

The values at every 5°, obtained by graphic interpolation, are given in the table towards the end of this paper. The boiling point (760 mm.), taken from the curve, is 382.5°.[1]

The Vapor Pressures of a Mixture of Calomel and Mercury.—The vapor pressure of the mixture was not observed directly, because a small error in temperature would have caused an error of many millimeters in the pressure. Instead, we measured the difference in pressure between the mixture and pure mercury, and small changes in temperature cause very slight alterations in this difference. The observed difference was then added to the vapor pressure of mercury at the same temperature. The chief source of error in the resulting observed pressures of the mixture lies, therefore, in the values of the vapor pressures of mercury. Now, the latter enter also as the chief term in the calculated pressures of the mixture, and in the final comparison of observed and calculated pressures of the mixture this error, therefore, largely disappears.

To accomplish the measurements of the difference, two static isoteniscopes, one containing pure mercury and the other containing the mixture, were immersed together in the bath, and were manipulated simultaneously. One was connected with the gage in the usual way. By means of a bent glass tube fused on to the long, open limb of the gage, the other isoteniscope was connected with the other side of this instrument. The pressures acted against one another, through the gage, and only the differences in pressure was shown.

In this instance, since there was free mercury mixed with the calomel, there was no objection to the use of mercury as the confining fluid. Hence, mercury was used as the confining liquid in both isoteniscopes.

The observed differences in pressure were as follows:

t	*p.*	*t*	*p*
326.7	13.0	386.3	94.4
356.6	36.7	393.9	118.5
374.9	66.8	397.8	135.5

---

[1] Jonker, *Chem. Weekblad.*, 6, 1035 (1909), finds 373°; Harris and Meyer, *Ibid.*, find 357°.

The following table gives the values of these differences at every 5°, obtained graphically, together with the vapor pressures of the mixture, secured by adding these differences to the vapor pressures of pure mercury at the same temperatures:

t.	Diff. ($P_{\text{mixt.}}$ —$P_{\text{merc.}}$).	$P_{\text{mixt.}}$, obsd.	t.	Diff. ($P_{\text{mixt.}}$ —$P_{\text{merc.}}$).	$P_{\text{mixt.}}$, obsd.
360°	41.0	843.6	385°	90.8	1321.7
365	48.2	924.9	390	105.7	1441.4
370	56.8	1013.0	395	123.7	1570.8
375	66.8	1108.4	400	147.3	1713.4
380	78.1	1211.1			

An Unexpected Complication of the Problem.—In order that the purpose of the experiments next to be described may be understood, a preliminary examination of the foregoing results is necessary. At 390° (data in final table), for example, the vapor pressure of mercury alone ($P_{\text{merc.}}$) is 1335.4 mm. and that of calomel ($P_{\text{calom.}}$) is 906 mm. Assuming complete dissociation, and substituting in equation 3,

$$p'_{\text{corros}} = \frac{(\frac{1}{2}P_{\text{calom.}})^2}{P_{\text{merc.}}} = \frac{453^2}{1335.4} = 153.7 \text{ mm.},$$

we obtain 153.7 mm. for the partial pressure of the mercuric chloride vapor in the mixture at 390°, as calculated, with the aid of the theory, from the vapor pressures of the substances observed separately. The directly observed value of the vapor pressure of mercuric chloride at this temperature, which, again assuming complete dissociation, is the difference between the vapor pressures of the mixture and of mercury alone, is only 105.7 mm. (see table above), a discrepancy of over 30 per cent.

The discrepancy is in an unexpected direction. The total pressure of the mixture, calculated on the assumption that there is no dissociation (equation 1) is 1335.4 + 906 = 2241.4 mm., and calculated on the assumption that dissociation is complete is 1335.4 + 153.7 = 1489.1. The observed pressure of the mixture is 1335.4 + 105.7 = 1441.1. If HgCl were present in the vapor, the total pressure would lie at some point between the two calculated values. The observed pressure is *lower* than the smaller of the two, and below the minimum indicated by the theory as thus far considered. HgCl certainly appeared to be proved absent, but before definitly drawing this conclusion it was desirable to account, if possible, for the lack of agreement between the calculated and observed values. A discrepancy of 48 mm. in a total of 1441 mm., or 3.3 per cent., is not unusual in vapor pressure measurements at high temperatures. But the precautions taken and the tests of the method which had been made, rendered it certain that the errors of observation were of nothing like this magnitude. The cause evidently lay in the nature of the substances.

The Density of Saturated Mercury Vapor.—In the first place, it will be noted that the laws of chemical equilibrium employed hold for the actual concentrations of the substances concerned. The *pressures* are substituted in the formulas, on the assumption that they are proportional to the molecular concentrations. Now, that assumption, which is equivalent to assuming that the substances have normal vapor densities, may not be correct in the particular cases under consideration. For example, it was possible that saturated mercury vapor might have an abnormally high vapor density, and that this substance, while being present in the molecular concentration required by the theory of chemical equilibrium, exercised a pressure less than that proper to its concentration. Thus, in the equation from which the partial pressure of mercuric

$$\frac{(\frac{1}{2}P_{\text{calom.}})^2}{P_{\text{merc.}}} = p'_{\text{corros.}},$$

chloride is calculated, the actual concentration of the mercury may be correct, but its pressure (in the denominator) may be too small. This would account for the calculated value of the whole expression being 153.7 mm., while the observed pressure of $HgCl_2$ is only 105.7 mm. That the density of the saturated mercury vapor should be thirty per cent. too high seemed unlikely, but some considerable part of the divergence might originate here.

The only published determinations of the density of saturated mercury vapor seem to be those of Jewett.[1] His work, however, only shows that the density is approximately normal. A divergence of four per cent. would not have been detected with certainty. Then, too, his observations only extended up to 325° where the vapor pressure is about half an atmosphere, and the divergence, if it existed, might be greater at the pressures of nearly two atmospheres occurring in these experiments. Some measurements were, therefore, made at 360 to 400° (pressures 800–1565 mm.). Jewett's method was used, with modifications in the apparatus calculated to insure a degree of accuracy of ±2 per cent., which was sufficient for the present purpose. The divergence was found to be only about 1 per cent. Hence, within the limits of accuracy of the method, the density is normal under these conditions. This hypothesis, therefore, would not account for divergence encountered in the calomel problem.

As the vapor density of saturated mercury vapor is worth studying on its own account, it is proposed to make a more accurate series of measurements in the near future.

The Density of Saturated Calomel Vapor.—Since the vapor pressure of the calomel enters into the numerator of the fraction, any abnormality in the density of the saturated vapor of this substance would involve a correction which would only increase the divergence of which an explanation was being sought. At the same time, the assumption, that concentration and pressure were proportional to one another, was so fundamental to the whole investigation that it seemed necessary to test it in each case.

---

[1] *Phil. Mag.*, [6] 4, 546 (1902).

The vapor density of saturated calomel vapor has never been determind. In the vapor density measurements of Mitscherlich (508°), Deville and Troost (445°), and V. Meyer and Harris (445° and 518°), made at atmospheric pressure, the vapor was much less than half saturated.

For the determination, a small bulb containing a known weight of calomel was fused on to the neck of a round-bottom flask, after the neck of the latter had been drawn out to a capillary and bent downwards (Fig. 1). The flask was exhausted to less than 0.01 mm. pressure through a side tube, which was then sealed off. The whole was immersed in a vigorously stirred bath of the melted nitrates of potassium and sodium, and the temperature was slowly raised to 352.5°, where it was maintained for ten minutes. The bulb was then raised so that, as the highly arched capillary tube emerged from the surface of the melt, it encountered a blowpipe flame which sealed the capillary. The method of sealing the communication between the bulb and the flask is very essential and was adopted after previous experience had shown that cooling the whole apparatus with this tube open (after the manner of Jewett's experiments with sodium) gave rise to slightly variable results. This variability was due, doubtless, to distillation, caused by unequal rates of cooling of the two very dissimilar parts of the apparatus. The weight of the calomel vapor was determind by finding the loss which the amount in the small bulb had sustained. The volume of the flask was measured by weighing full of air and of water, with reduction to vacuum, and was corrected for the expansion of the glass at 352°. The temperature was ascertained with a nitrogen-filled mercury thermometer[1] and was fully corrected. The vapor pressure of calomel, as determind with the same instrument, was therefore employed (352 mm. at 352.5°). The measurement is accurate within less than ±2 per cent., which was sufficient for the purpose. The densities were: observed 0.002169, calculated 0.002125, and their ratio 1.02. The density was therefore normal, within the errors of measurement.

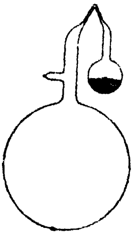

Fig. 1.

Other measurements of the density of saturated calomel vapor have since been made for another purpose, and will be published in another paper. The values confirm the conclusion that the density is normal.

---

[1] The thread was almost completely immersed.

The Density of the Mixed Vapors.—Since it thus appeared that the densities of the substances, when separate, were normal, it followed that the main divergence was due to some factor affecting the vapor pressure of the mixture, and such as to make the observed value nearly 4 per cent. lower than the calculated value. It seemed possible that, although the substances when separate showed normal vapor densities, yet when mixed they might influence one another so as to cause the mixture to have an abnormally high density, and therefore an abnormally low vapor pressure The density of the mixed vapors was therefore determind, using the same methods as for calomel, excepting that two bulbs were attached to the flask, one for each substance. As the data are not of permanent value, the details of the experiments and calculations need not be given. It is sufficient to say that the ratio of the densities found and calculated was 1.02, with an accuracy of ±2 per cent. There was therefore no abnormality which could account for the divergence.

The Solubility of Calomel Vapor in Mercury.—There remained the possibility that, in spite of appearances, calomel might be somewhat soluble in mercury at the temperature concerned. If this turned out to be true, the vapor pressure of the mercury in the mixture would be lowered by the influence of the dissolved calomel, and the total vapor pressure of the mixture would be diminished. A lowering of the vapor pressure of the mercury (1335.4 mm. at 390°) by about 50 mm. would account for the divergence observed. A solubility of the chloride of a metal in the metal itself is not known to occur in many instances, but has been established in the case of bismuth trichloride.[1]

A number of preliminary experiments showed that calomel did dissolve in mercury. They showed also that the complete saturation of a mass of mercury by calomel vapor was an exceedingly slow process even at 360-400°, and that the use of small amounts of mercury, of continual agitation by the vibrations of the stirring apparatus, and of 5-6 hours' time were required for the attainment of the maximum, constant values.[2] The apparatus (Fig. 2) consisted of a small bulb (vol. only 1 cc.) containing a weighed portion of mercury (about 0.5 to 1 g.). The calomel in known amount was contained in a small tube, shown in section and front view in Fig. 2, A. and B. After the calomel tube had been introduced,

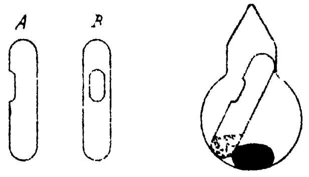

Fig. 2.

---

[1] Eggink, *Z. physik. Chem.*, 64, 449

[2] In the vapor pressure measurements themselves, the fully lowered pressures had been immediately attained This was doubtless due to the fact that the pressures observed proceeded from the fully saturated surface layer of mercury.

the bulb was exhausted to less than 0.1 mm. pressure and sealed. After the charged apparatus had been heated 5–6 hours at the required temperature, it was opened. The loss in weight of the calomel tube gave the quantity dissolved by the mercury, for the weight required to fill the 1 cc. bulb, as vapor, was negligible. At 398°, for example, three observations gave the following results:

Mercury taken. Gram.	Calomel dissolved.	Parts Hg to 1 pt. calom.
1.3118	0.0622	21.1
0.8796	0.0404	21 8
0.4997	0.0237	21.1
	Mean,	21 33

The possibility that the solubility might be reciprocal, and that mercury might dissolve in calomel, was considered. It was observed that the residual calomel, when cold, was perfectly white and showed no evidence of the presence of mercury. In some of the experiments, also, care was taken to use different relative amounts of calomel and of mercury at the same temperature. A little consideration will show that, in such circumstances, if mercury had been appreciably soluble in calomel, constant results for solubilities, calculated as described above, would not have been obtained. It is clear, therefore, that the solubility of mercury vapor in calomel is too slight to require consideration.

For calculation of the lowering in vapor pressure of the mercury, the solubilities must be expressed in numbers of molecules of each substance. If we take HgCl as the formula of the dissolved calomel, the foregoing value at 398° corresponds to 1 mol. HgCl to 25.11 mols. mercury. If, however, the formula is Hg_2Cl_2, then the ratio becomes 1:50.22. If as is conceivable at this high temperature, calomel is unstable, even in solution in mercury, and $HgCl_2$ is the dissolved substance, the ratio is 1:51 22. For reasons which will appear presently, the first ratio was taken.

The solubility was measured at three temperatures. The ratios of molecules of mercury to 1 molecule of HgCl found were as follows: 398°, 25.11; 379°, 26.36; 360°, 39.56. These values were plotted, and the solubilities at even temperatures read from the curve are given in the table following.

The Final Results.—From these experiments it is evident that the partial pressure of mercury vapor in the mixture is not that of pure mercury ($P_{\text{merc.}}$), but that of the solution of calomel in the latter (say $P'_{\text{merc.}}$). For example, at 390°, the value is not 1335.4, but a smaller value. At this temperature the molecular solubility is 1HgCl: 25.4Hg. The partial vapor pressure of mercury over this solution is in proportion to the number of molecules of mercury in the total molecules present; that is to say, it is 1335.4 × 25.4 ÷ 26.4, or 1284.8 mm. Substituting this value for $P_{\text{merc.}}$ in equation 3, we obtain $(^1/_2\,906)^2 \div 1284.8$ = partial pressure of mercuric chloride in the mixture = 159.7. This value, plus the vapor pressure of the mercury as lowered by calomel should equal the observed pressure of the mixture: 159.7 + 1284.8 = 1444.5. The observed pressure of the mixture at this temperature was 1441.4. When the number of measurements involved in the former of these numbers, and the difficulties connected with making exact vapor pressure determinations are taken into account. it will be seen that this agreement within 3.1 mm. in a total of 1444 mm. is much closer than there was any reason to expect. At the other temperatures the degree of agreement is of the same order. It is evident, therefore, that the complete dissociation of calomel vapor, and the absence of HgCl from the vapor, the assumptions underlying equation 3, are satisfactorily established.

The following table contains the complete data. Column 7 shows the vapor pressures of the mixture as calculated by equation 3 from the vapor pressures of calomel (col. 5), and of mercury (col. 4), the latter as depressed by dissolved calomel. Column 8 contains the observed vapor pressures of the mixture. Column 9 gives the differences between the calculated and observed values. The greatest divergence is 6.8, the smallest 0.4, the sum is —0.9, and the deviation of the observations as a whole from the calculated values is only —0.1 mm. It will be noted that, within the range of temperatures covered, the pressure of the mixture has more than doubled itself, but the divergencies show no tendency to progressive change. The average divergence is less than 1 part in 12000. This excellent agreement with the theory that only Hg and $HgCl_2$ are present in the vapor of calomel demonstrates conclusively, within the limits of error of the method, the complete absence alike of HgCl and of Hg_2Cl_2 from the saturated vapor:

1 t	2 Sol'ty $\frac{\text{mols. Hg}}{\text{1 mol. HgCl.}}$	3 $P_{\text{merc.}}$	4 $P'_{\text{merc.}}$, dep by calom.	5 $P_{\text{calom.}}$	6 $p'_{\text{corros.}}$ calc	7 P_{mixt}, calc. 4+6	8 P_{mixt}, obsd.	9 Divergence 8-7
360	39.6	802.6	782.8	434	60.1	843.0	843.6	0.6
365	32.6	876.7	850.6	491	70.9	921.5	924.9	3.4
370	29.3	956.2	924.7	556	83.6	1008.3	1013.0	4.7
375	27.3	1041.6	1004.8	630	98.7	1103.6	1108.4	4.9
380	26.2	1133.0	1091.4	712	116.1	1207.5	1211.1	3.6
385	25.6	1230.9	1184.6	805	136.8	1321.3	1321.7	0.4
390	25.4	1335.4	1284.8	906	159.7	1444.5	1441.4	—3.4
395	25.2	1447.0	1391.8	1017	185.8	1577.6	1570.8	6.8
400	25.1	1566.1	1506.1	1135	213.9	1719.9	1713.4	—6.5

Calculation of the partial pressures of HgCl, by means of equation 4, leads, of course, to the same conclusion. The values found vary on each side of zero, being for the nine temperatures, 0.9, 4.8, 6.8, 7.0, 5.3, 0.5, —5.3, —10.7, and —10.5 mm. The average of the nine is —0.13

mm., and differs therefore from zero by much less than the errors of measurement.

Results with a Mercury Thermometer.—As the platinum resistance thermometer is a difficult instrument to handle, and is not always available, it is worth while to show that the problem might have been solved and the same conclusion reached with the simplest apparatus. With a good nitrogen-filled thermometer, the actual values of the temperatures between 360 and 400° (and the corresponding pressures) are not exceedingly accurate, as, in spite of careful correction, the individual temperatures taken with such a thermometer may be in error as much as ±1°. But when, as in this case, the same thermometer and the same conditions are used in each of the three series of vapor pressure measurements, the errors partly cancel one another and the results may be useful in spite of them.

In the preliminary experiments, the vapor pressures of mercury, calomel, and the mixture had been determind between 360 and 395° with such a thermometer. The simple, submerged bulblet, vapor pressure apparatus[1] was employed, with a good gage. The solubility measurements given above were the only parts of the better data used in the calculation of the results. The individual values of the pressures, being less accurate, need not be given. The greatest divergence in the final results between theory and calculation was 6 mm. and the smallest 1 mm. The average divergence of the results as a whole from the theory of complete dissociation was only −3.3 mm. Problems of this kind can therefore be solved even by the use of the submerged bulblet apparatus and a mercury thermometer.

The Molecular Weight of Calomel in Solution in Mercury.—In the discussion of the theory of the method it was pointed out that three independent observations were required to demonstrate the constitution of calomel vapor. It turned out, however, that the dimensions of the molecular weight of calomel in solution in mercury was an additional unknown quantity, the presence of which, as a part of the problem, was not foreseen. At least one more independent observation is therefore logically necessary to establish the fact that the dissolved calomel is monomolecular. It will be noted, however, that instead of only three observations, three groups of observations, covering a wide range of pressures, were made. The experimental material is therefore amply sufficient to sustain this additional conclusion.

If we assume, for the moment, that the dissolved calomel is bimolecular (Hg_2Cl_2), the ratios of molecules of mercury to molecules of calomel (col. 2) are all doubled. This alters the proportions of mercury molecules to total molecules (*e. g.*, at 390° to 50.8:51.8), and therefore the calculated partial pressures of the mercury in the solution. Figuring on this basis, the final divergencies between calculated and observed data (col. 9) now become —12.2, —9.7, —11.1, —13.5, —18.0, etc., up to —36.6 at 400°. The excellent correspondence thus disappears, and the divergencies increase rapidly with ascending temperature.

---

[1] THIS JOURNAL, 32, 907. It is worth noting that this method is dynamic, while the one used in the main series was static.

Conclusions.—1. A series of vapor pressures of calomel from 360 to 400° has been obtained. The boiling point is found to be 382.5°.

2. It has been shown by a quantitative vapor pressure method (static), that calomel vapor, even when saturated, is wholly dissociated, and that molecules of the classes HgCl and Hg_2Cl_2 are not present.

3. Independent measurements, with an apparatus working on the dynamic principle, lead to the same conclusion.

4. It has been shown that the molecular weight of calomel dissolved in mercury at 360–400° corresponds to the monomolecular formula, HgCl.

5. It has been shown that, by the use of the isoteniscope, chemical problems can be investigated, and results can be obtained, possessing the same order of accuracy that is claimed for the most refined methods of quantitative analysis.

[CONTRIBUTIONS FROM THE RESEARCH LABORATORY OF PHYSICAL CHEMISTRY OF THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY, NO. 60.]

TRANSFERENCE EXPERIMENTS WITH THALLOUS SULPHATE AND LEAD NITRATE.

BY K. GEORGE FALK.

Received September 28, 1910.

CONTENTS.—1. Introduction. 2. Apparatus. 3. Description of the Experiments with Thallous Sulphate. 4. The Transference Data for Thallous Sulphate. 5. Description of the Experiments with Lead Nitrate. 6. The Transference Data for Lead Nitrate. 7. Discussion of the Results. 8. Summary.

1. Introduction.

In a paper published some years ago, A. A. Noyes[1] pointed out that the change of the transference number of tri-ionic salts with the concentration might be expected to throw light on the question as to whether intermediate ions, such as KSO_4^- in the case of potassium sulphate, or NO_3Ba^+ in the case of barium nitrate, existed in appreciable quantities in solutions of such salts. Results for potassium sulphate, barium chloride, and barium nitrate were published. In this paper, the results obtained with two other salts of this type, thallous sulphate and lead nitrate, will be given; and the theoretical significance of the transference results will be considered.

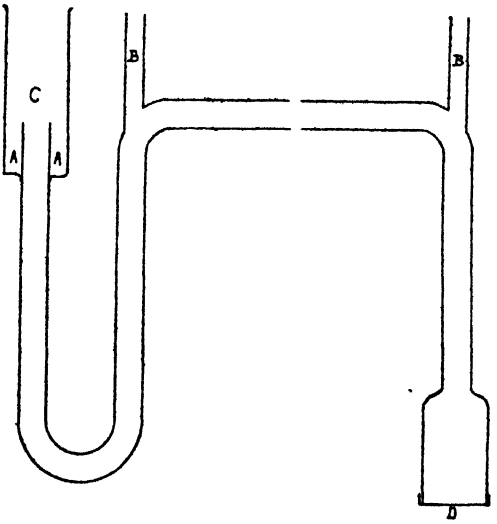
[1] THIS JOURNAL, 23, 37 (1901).

This investigation was undertaken at the suggestion of Prof. A. A. Noyes, and was carried out with the aid of a grant made to him by the Carnegie Institution of Washington.

2. Apparatus.[1]

A cross section of the apparatus, drawn to scale but reduced to 1/5 its natural size, is shown in the accompanying sketch.

The U tube served as the cathode side. The cathode itself rested in the annular space AA in the compartment C. It consisted of an annular strip of sheet platinum fused to a platinum wire, which in turn was fused into a piece of small glass tubing containing mercury, which passed through a rubber stopper closing that side of the apparatus. The diameter of the glass tube throughout the apparatus was 1.5 cm., except at the electrodes, where it was widened to 3.5 cm.



The anode part consisted of the straight tube with the side arm. The widened part at the lower end was closed by fitting over it a gold cup, D. Gold was used instead of platinum because it was easier to work into shape and gave a closer fit. Ceresin was poured in between the upper edge of the cup and the glass, and the joint was covered with two layers of rubber tubing securely wired on. The bottom of the cup was insulated from the bath by a large rubber stopper held up against it by the rubber tubing, which extended sufficiently far down for this purpose. Electric connection with the bottom of the cup was made by a small sheet of platinum pressed against it and fused to a platinum wire which passed through a glass tube in the stopper. The platinum wire was connected below to a copper wire, which was enclosed in black rubber tubing and led up through the bath.

The cathode and anode parts of the apparatus were joined by a double layer of rubber tubing wired in several places and covered with ceresin.

---

[1] To Mr. A. C. Melcher, who rendered valuable assistance in the preparation of the apparatus and development of the experimental method, the writer desires to express his indebtedness.

The two parts were brought so near together that there was practically no free space betwen the glass.

The tubes BB, 1 cm. in diameter, served to introduce or remove the solutions.

The current was taken from the 110-volt city circuit with a sufficient number of 32-candle power 220-volt lamps in series to give the strength of current desired, as shown by a milliammeter placed in series with the apparatus.

The current was measured accurately by means of two silver coulometers, each consisting of a platinum dish 7 cm. in diameter as cathode, a silver disk riveted through its center to a silver rod and wrapped in filter paper as anode, and a 15 per cent. silver nitrate solution as electrolyte. The two coulometers were introduced into the circuit at opposite ends of the transference apparatus, thus guarding against error from leakage of electricity.

3. Description of the Experiments with Thallous Sulphate.

In carrying out the experimental determinations of the transference number of thallous sulphate, a current of electricity was passed through the solution of this salt for a certain length of time, using a definit weight of thallium as anode and allowing thallium to be deposited on the platinum plate at the cathode. The thallium at the two electrodes was dissolved after the experiment and added to the respective electrode solutions; and these were then analyzed. The middle portions were also analyzed, in order to determin whether the changes in concentration extended into them. In this way a theoretically perfect method was attained; for only thallous sulphate was present in the solution, even in the neighborhood of the electrodes; and both the electrode portions, as well as all the middle portions, were analyzed.

The detailed description of the experiments may for convenience be divided into four parts: (1) preparation of the solution; (2) preparation of the anode; (3) electrolysis of the solution and removal of the portions; and (4) analysis of the portions.

Preparation of the Solution.—Kahlbaum's thallous sulphate was used. Though it apparently contained no impurity, it was crystallized from conductivity water. The solutions were made up approximately 0.1 and 0.03 normal with conductivity water, and the exact strength determined gravimetrically as described below. The average of four or five results was adopted as the content of each solution. The solutions used were tested repeatedly with litmus and found to be neutral; and a 0.02 normal solution was more accurately tested with rosolic acid, showing that the solution was no more acid than the water used in preparing it.[1]

---

[1] Reference is made to this fact since Denham (*J. Chem. Soc.*, 93, 59 (1908)) states that his thallous sulphate solution was acid and was largely hydrolyzed.

Preparation of the Anode.—The anode was prepared by depositing electrolytically an accurately known weight of thallium in the gold cup. The procedure differed slightly for the 0 1 and 0 03 normal solutions. In the former case, about thirty grams of the thallous sulphate solution, the exact amount being immaterial, were poured into the anode compartment; about 1 3 grams (accurately weighed) of dilute sulphuric acid were added; and the solution was electrolyzed, with the gold cup as cathode and a small platinum wire as anode, for about 2 hours with a current of 0 030 to 0.040 amperes. Metallic thallium deposited on the cup, and oxygen was evolved at the platinum wire; but at the same time a very small amount of thallic hydroxide deposited on the latter. The presence of the sulphuric acid prevents the formation of all but a minute quantity of thallic hydroxide, whereas the addition of a considerably larger quantity of sulphuric acid would prevent the deposition of metallic thallium. After a sufficient quantity (about 0 5 gram) of thallium had been deposited, the solution was drawn by suction directly into a weighed flask, the platinum wire and the apparatus containing the deposited thallium were washed three times with successive portions of the original solution, and the washings were transformed to the weighed flask. This was then weighed; and the thallium in the solution was determined, after dividing the liquid into two portions so as to obtain check results. By subtracting this weight of thallium from that originally associated with the quantity of water[1] present in the analyzed solution, the quantity of thallium deposited on the gold cup could be accurately determined (within 0 1 mg.).

For the 0.03 normal solution, some slight modifications were necessary. About 40 to 50 grams of the original solution were used for electrolysis and no sulphuric acid was added, since not enough thallic hydroxide formed to interfere with the experiment. The electrolysis was continued only for an hour, as the solution then became exhausted and hydrogen began to be evolved. Duplicate analyses were not made, as there was not enough thallium present in the solution to permit of it. The thallium deposited amounted to about 0 2 gram.

Electrolysis of the Solution.—After the preparation of the thallium deposit on the anode, the apparatus was charged with the solution so that the cathode compartment, C, was filled to three-fifths of its height, air bubbles in the horizontal portion were dislodged, and the apparatus placed in a thermostat at 25°, only the upper ends (two centimeters) of the tubes BB and of the cathode tube being above the surface of the water. The tubes were closed with rubber stoppers, and electric connection was made with the cathode by the column of mercury contained in the glass tube.[1]

---

[1] This quantity of water was calculated by subtracting from the weight of the analyzed solution that of the thallous sulphate found to be present in it, that of the dilute sulphuric acid added, and that of the SO_3 produced by the electrolysis (according to the reaction $Tl_2SO_4 = Tl + 1/2O_2 + SO_3$). The last quantity was calculated from the weight of thallium deposited, after this had been found approximately by a preliminary computation.

The apparatus was allowed to remain in the thermostat long enough to attain its temperature (25°) before starting the current. The electrolysis was continued for three hours or somewhat longer. The approximate strength of the current (as shown by the milliammeter) for the more concentrated solution was 0 012 amperes in the first experiment and 0 015 in the second; for the dilute solution in all three experiments, 0 007 amperes. During the electrolysis no bubbles of gas were evolved at either electrode; and at the end of it the electrode portions were both neutral to litmus.

At the end of the electrolysis the stoppers in the tubes BB were taken out, and the middle portions were drawn out by suction through glass tubes bent at two right angles directly into weighed flasks. In the experiments with the more concentrated solution three middle portions were taken, one consisting of the liquid contained in the horizontal part of the apparatus, one of the liquid in the vertical arm of the cathode side of the apparatus down to the bend, and one of the liquid in the vertical part of the anode side of the apparatus down to one centimeter above the anode compartment. These solutions were weighed and analyzed. In the experiments with the more dilute solution, two middle portions were taken, one consisting of the liquid in the horizontal part and in the upper half of the vertical arm on the anode side, the other of the liquid in the vertical arm on the cathode side down to the bend.

After the removal of the middle portions, the apparatus was taken from the thermostat, and the two parts were disconnected and closed by stoppers. After being dried on the outside the two parts were weighed separately to the nearest centigram

The cathode portion was poured into a flask, and the apparatus washed several times with water, the washings being added to the flask. The thallium deposited on the cathode was dissolved in sulphuric acid and this solution united with the other. Duplicate determinations of the thallium present in known fractional parts of this solution were then made. The apparatus was dried and weighed, together with the stoppers and cathode, so as to obtain the total weight of the cathode portion before it was diluted (including the deposited thallium). The weight of water present in the cathode portion was calculated by subtracting from its total weight that of the thallium[1] and thallous sulphate. From this the amount of thallium in the original solution associated with this quantity of water could be found, whereby the amount of thallium transferred by the current became known.

---

[1] Attempts were made to use as cathode mercury containing a very small quantity of zinc, as recommended by Morden (THIS JOURNAL, 31, 1045 (1909)), but it was found that the zinc rapidly replaced the thallium in the aqueous solution.

With the anode portion, the procedure was similar. After weighing the part of the apparatus containing it, the solution was poured into a flask, the thallium remaining on the anode was dissolved in sulphuric acid either directly or by passing a current through the solution with the cup as anode, and this solution, as well as the water used to rinse the apparatus, was added to the flask and duplicate analyses of known fractions of this solution were made. The anode part of the apparatus was dried and weighed, thus giving the weight of the anode solution plus the thallium remaining on the anode. Assuming the thallium to dissolve according to Faraday's law, and knowing the amount of thallium deposited on the anode originally, the weight of water in the anode portion was calculated, and from that the amount of thallium which originally was present in the solution and on the anode and also the amount of it transferred was determined.

Analysis of the Solutions.—The method of analysis employed was in all cases the determination of the thallium by precipitating and weighing it as thallous iodide. The original solution and the middle portions when analyzed were perfectly neutral toward litmus; the electrode portions had been made acid with dilute sulphuric acid. To the latter, to provide for any oxidation to the thallic state that might have occurred, a few cubic centimeters of a 5 per cent. potassium sulphite solution were added before the precipitation. The solution of thallous sulphate was heated to boiling and a 5 to 10 per cent. solution of potassium iodide, also heated to boiling, was added with stirring. Sufficient iodide was added so that the solution, after precipitation, contained two per cent. or more of potassium iodide. The solution was then boiled vigorously for about a minute, so as to break up the lumps of thallous iodide and enable it to be filtered and washed more readily. The iodide as first precipitated was orange in color, but very soon became light yellow. The solution was allowed to stand overnight, the precipitate collected on a platinum Gooch crucible, washed with about 100 cc. of a 2 per cent. potassium iodide solution until free from sulphate and then with 80 per cent. alcohol to remove the potassium iodide. The precipitates were heated at 160° for an hour, which, as preliminary experiments proved, was sufficient to ensure a perfectly constant weight.

Duplicate analyses in almost all the cases checked within 0.1 per cent., and the method of analysis may therefore be considered accurate to that degree. The presence of sulphuric acid up to the amount used had no apparent influence. The amount of thallous iodide weighed was between 0.3 and 1.2 grams.

---

[1] In making this correction the thallium deposited was assumed to be equivalent to the silver precipitated in the coulometers.

4. The Transference Data for Thallous Sulphate.

The experimental data are given in Tables I and II. The headings are sufficiently explanatory, or become so when considered in connection with the description given above. The letters in the second column have the following significance: PA, Solution from which the thallium was deposited in preparing the anode. A, Anode solution. M_A, Middle portion adjoining the anode solution. M, Middle portion. M_C, Middle portion adjoining the cathode solution. C, Cathode solution. In the case of the 0 02999 normal solution there were only two middle portions, which are designated M_A and M_C, respectively. The changes

in concentration in the portions adjoining the electrode portions were in all cases within the experimental error of the analyses, and they have therefore not been included in the changes in concentration of the electrode portions.

A number of experiments were made which were faulty in one respect or another; for example, because of a leak of the current between the coulometers, or of unsatisfactory preparation of the thallium deposit on the anode. None of these experiments are reproduced here; but all of those are included in which from external evidence alone, without considering the results, the process appeared to be successful.

Mr. F. L. Hunt working in this laboratory found d_4^{25} = 1.0204 for a solution containing 0.1 equivalent of thallous sulphate in 1 liter solution.

The values of the transference numbers are summarized in Table III. Since there seems to be no error in the method that would tend to make the results at either electrode either too high or too low, and since there was less manipulation involved in the treatment of the cathode than of the anode portion, it seems best to derive the final values of the transference number by taking the mean of the cathode and anode results with double weight assigned to the former. Taking into consideration the variation of the cathode and anode results and the fact that almost all errors are likely to affect them in opposite directions, it seems very improbable that the final values are in error by more than 0.5 per cent.

5. Description of the Experiments with Lead Nitrate.

The apparatus which was used in the transference experiments with thallous sulphate was also used in those with lead nitrate. Except for a few modifications which will be described, the experimental method was essentially the same.

Preparation of the Solution.—Kahlbaum's lead nitrate, recrystallized from conductivity water to which 1 per cent. nitric acid had been added, was used. Solutions approximately 0.1 and 0.03 normal were prepared with conductivity water, and the exact contents determined gravimetrically. These solutions showed a neutral reaction.

Preparation of the Anode.—Finely granulated "test lead," such as is used in assaying, was employed in preparing the anode. It was found by analysis to contain 99.83 per cent. lead, with small amounts of oxide and moisture. A known weight was placed in the gold cup of the apparatus before adding the solution.

Electrolysis of the Solution.—The procedure was the same as with thallous sulphate, except that the lead which remained undissolved at the anode after the electrolysis was dissolved in nitric acid and added to the anode solution after the apparatus had been dried and weighed. It is therefore not included in the weights of anode solutions given in the tables. The electrode solutions remained clear during the passage of the current; but after their removal from the apparatus they became cloudy in a few minutes on account of lead hydroxide formed from the finely divided lead and the oxygen of the air. This shows that nitric acid was not formed at either electrode. The weight of lead which dissolved at the anode and separated at the cathode was assumed to be equivalent to the weight of silver separated in the coulometers. The weight of lead used as anode given in the tables is the calculated weight of pure lead (*i. e.*, the weight of the test lead multiplied by 0 9983).

Analysis of the Solutions.—The lead was precipitated and weighed as lead chromate in all cases. In the case of the neutral solutions, 1 cc. of a 10 per cent. sodium acetate solution and 10 cc. of a 5-fold normal acetic acid solution were added, and the hot solution was precipitated with a one or two per cent. potassium dichromate solution, about 50 per cent. in excess of that required for precipitation being employed. The solutions containing the precipitates were allowed to stand at least 12 hours; the lead chromate was then collected on a platinum Gooch crucible, washed with 200 to 300 cc. water, and dried at 160–170°. To the solutions which contained free nitric acid, either an excess of sodium acetate was added (experiments 1–3), or sodium carbonate solution was added until the acid was neutralized (experiments 4–7), and then acetic acid and dichromate were added as before. Duplicate analyses were found to agree much more satisfactorily when the precipitates were amorphous in character and settled slowly, than when they were crystallin and the solutions cleared rapidly, which last was the case when insufficient sodium acetate was added. Duplicate analyses checked within 0.1 per cent. except in case of some of the dilute solutions (experiments 4–7).

6. The Transference Data for Lead Nitrate.

The data and calculated results are given in Tables IV and V. The changes in the middle portions have not been included in the calculated changes of the electrode portions in any case:

TABLE VI.—SUMMARY OF THE CATION TRANSFERENCE NUMBERS FOR LEAD NITRATE AT 25°.

	0.1002 normal.			0.02994 normal.	
	Cathode.	Anode.		Cathode	Anode.
	0.494	0 481		0 481	0 489
	0.488	0 493		0 492	0 502
	0.480	0 489		0 489	0 478
	----	---		0 481	0.486
Mean,	0 4873	0 4877		---	----
Final value,		0 4875	Mean,	0 4858	0 4889
			Final value,		0 4874

The results are summarized in Table VI. In deriving the final values equal weight has been given to the results obtained from the anode and cathode solutions. It is hardly possible that the error in these final values exceeds ±0 003 or 0 6 per cent.

7. Discussion of the Results.

An examination of the final values given in Tables III and VI shows that for either salt between the concentrations 0 03 and 0.10 normal there is no variation (greater than the probable experimental error) in the transference number of the cation Within this range of concentration the values **0 477** (±0 003) for thallous sulphate, and **0 487** (±0 003) for lead nitrate may therefore be adopted.

It is of interest to compare these values with those at zero concentration which may be calculated from the equivalent conductances of the separate ions. For the ions in question Kohlrausch[1] has derived the following values:

---

[1] *Landolt-Bornstein-Meyerhoffer Tabellen*, p 763 (1905), also *Z Elektrochem.*, **13,** 342 (1907) The values at 25° have been calculated with the aid of Kohlrausch's temperature coefficients A partially independent determination of Λ_{Tl} and Λ_{SO_4} from new data upon the conductance of potassium sulphate and thallous sulphate at 18° and 25° recently obtained in this laboratory has led to the following values at 25°: $\Lambda_{Tl} = 76\ 0$ and $\Lambda_{SO_4} = 80\ 0$ These are seen to be closely concordant with those of Kohlrausch

At 18°: $\Lambda_{Tl} = 66.0$; $\Lambda_{SO_4} = 68.4$; $\Lambda_{Pb} = 61.0$; $\Lambda_{NO_3} = 61.7$.
At 25°: $\Lambda_{Tl} = 75.9$; $\Lambda_{SO_4} = 79.3$; $\Lambda_{Pb} = 71.4$; $\Lambda_{NO_3} = 70.6$.

From these values one obtains for the cation transference number, at 25°, 0.489 for thallous sulphate and 0.503 for lead nitrate. These values are 2.5 and 3.2 per cent., respectively, higher than those directly measured at the higher concentrations. It is not certain whether these differences are real or are due to errors in the values at zero concentration, which are based on extrapolations in the cases of two different types of salts. The fact that there is little, if any, change between 0.10 and 0.03 normal makes it somewhat improbable that there is any considerable change below 0.03 normal.

Assuming that the change is real, it might be due in the case of thallous sulphate to the presence of the intermediate ion $TlSO_4^-$ in the more concentrated solutions. In the case of lead nitrate, on the other hand, the presence of the intermediate ion NO_3Pb^+ would probably cause a change in a direction opposite to that of the observed one.

The effect of the intermediate ion depends, however, on the value of its equivalent conductance, as will be seen from the following values of the transference number for thallium (T_{Tl}) which have been calculated for the two limiting cases, where the only ions present are (1) Tl^+ and $SO_4^{=}$, and (2) Tl^+ and $TlSO_4^-$, by the expressions (1) $T_{Tl} = \Lambda_{Tl}/(\Lambda_{Tl} + \Lambda_{SO_4})$, and (2) $T_{Tl} = (\Lambda_{Tl} - \Lambda_{TlSO_4})/(\Lambda_{Tl} + \Lambda_{TlSO_4})$, for various relative values of Λ_{Tl}, Λ_{SO_4}, and Λ_{TlSO_4}.

	Case (1).	Case (2).
For $\Lambda_{Tl} = \Lambda_{SO_4} = \Lambda_{TlSO_4}$:	$T_{Tl} = 0.50$;	$T_{Tl} = 0.0$.
For $\Lambda_{Tl} = \Lambda_{SO_4} = 2\Lambda_{TlSO_4}$:	$T_{Tl} = 0.50$;	$T_{Tl} = 0.33$.
For $\Lambda_{Tl} = \Lambda_{SO_4} = 3\Lambda_{TlSO_4}$:	$T_{Tl} = 0.50$;	$T_{Tl} = 0.50$.
For $\Lambda_{Tl} = \Lambda_{SO_4} = 4\Lambda_{TlSO_4}$:	$T_{Tl} = 0.50$;	$T_{Tl} = 0.60$.

Identical values would obviously be obtained for the transference number of the nitrate-ion ($T_{NO_3} = 1 - T_{Pb}$) in lead nitrate for the corresponding assumptions that $\Lambda_{Pb} = \Lambda_{NO_3} = 1$ to $4\ \Lambda_{NO_3Pb}$.

These values show that for the case that $\Lambda_{Tl} = \Lambda_{SO_4} = 3\Lambda_{TlSO_4}$ or $\Lambda_{NO_3} = \Lambda_{Pb} = 3\Lambda_{NO_3Pb}$ the presence of the intermediate ion would have no influence on the transference number; and, if it be admitted that the value of Λ_{TlSO_4} or Λ_{NO_3Pb} can be as small as this, no positive conclusion can be drawn from the results. Unfortunately, no direct information is at hand as to the values of these ion-conductances, and they can be estimated only on the basis of kinetic considerations or of analogies with other ions of corresponding molecular complexity. Comparing the $TlSO_4^-$ ion with the $SO_4^{=}$ ion, or the NO_3Pb^+ ion with the Pb^{++} ion, it is evident that, since the electric charge on the former ion is only half as great, the driving force would be only half as great, and that therefore, assuming the ion is of the same size, its velocity and equivalent conductance would also be half as great. If, however, the intermediate ion is formed by direct union of the Tl^+ and SO_4^{--} or the Pb^{++} and NO_3^- ions, it might be expected that the ion would be larger than either of its constituents, so that its equivalent conductance would be less than one-half, and might well be approximately one-third, as great as that of the simpler bivalent ion.[1] It is, on the other hand, not improbable that the union of the simple bivalent and univalent ions to form the univalent intermediate ion is attended with a dehydration, since the relatively small conductance of the simpler bivalent ions indicates that they are, as a rule, more highly hydrated than the univalent ones. If this is the case, the conductance of the intermediate ion might have any value less than that of the constituent univalent ion. Of ions of composition and complexity analogous to $TlSO_4^-$ the hydrosulphate ion (HSO_4^-) and ethyl sulphate ion ($C_2H_5SO_4^-$) seem to deserve especial consideration. For the former, at 25°, Noyes and Stewart[2] have recently concluded that the value lies between 35 and 40, and for the latter Loeb and Nernst[3] found the value 39, while that for $SO_4^=$ is 79.3. Judging from these analogies, the value for $TlSO_4^-$ might also be about one-half that for SO_4.

These statements make clear how the matter stands. The fact that the transference numbers of both thallous sulphate and lead nitrate show little if any change with the concentration up to 0.1 normal does not prove that the intermediate ions of these salts are not present in considerable quantity at the latter concentration, for it is possible that the

---

[1] Prof. G. N. Lewis has suggested the following hypothesis, which requires in the special case here considered that the conductance of the intermediate ion be one-third that of the constituent ions, and which requires in general that the conductance of the intermediate ion has such a value that the transference number would not be influenced by its presence "By the dissociation of a strong electrolyte the typical physical properties (optical, thermal, volume, etc.) suffer no appreciable change. This is also true of the further dissociation of such intermediate ions as KSO_4^-, $BaNO_3^+$, if they exist. It would not, however, be true of such ions as $HC_2O_4^-$ or HSO_4^-, the dissociation of which is attended by a noticeable heat change. The intermediate ions of the former class are probably loose aggregates in which the constituent parts are not in such intimate proximity as to effect their individual properties. It may be assumed, therefore, that their constituents will show the same resistance to motion through the solution as they show when free. Considering now a salt A_2B yielding the ions A^+, B^{--}, and AB^-, whose specific resistances are represented by R_A, B_B, R_{AB}, this assumption requires that $R_{AB} = R_A + R_B$, and that the corresponding mobilities be

$$\Lambda_A = \frac{1}{R_A},\ \Lambda_B = \frac{2}{R_B},\ \text{and}\ \Lambda_{AB} = \frac{1}{R_A + R_B} = \frac{1}{\frac{2}{\Lambda_B} + \frac{1}{\Lambda_A}} = \frac{\Lambda_A\Lambda_B}{2\Lambda_A + \Lambda_B}.$$

This can be shown to be the general condition that the transference number is independent of the amount of intermediate ion. In the special case in which $\Lambda_A = \Lambda_B$, it is obvious that $\Lambda_{AB} = {}^1/_3\Lambda_A$."

[2] THIS JOURNAL, 32, 1142 (1910).

[3] *Z. physik. Chem.*, 2, 962 (1888).

conductance of these ions has such a value as to make the transference numbers independent of the character of the ionization. Unless some general hypothesis, like that suggested by Lewis, can be substantiated, it is somewhat improbable that the conductance should have this unique value, which is less than that for other univalent ions of similar complexity, in the case of any one salt; and it becomes more improbable that this should be true in the case of a number of different salts. Yet this investigation and the previous one[1] made in this laboratory have shown that four different tri-ionic salts, potassium sulphate, thallous sulphate, barium nitrate, and lead nitrate, all show the same substantial constancy of the transference numbers up to a moderate concentration.[2] Some degree of probability therefore attaches to the hypothesis that such tri-ionic salts do not as a rule give rise to intermediate ions, at any rate in quantity exceeding a few per cent. at 0.1-0.2 normal; but that they dissociate directly into three ions. At any rate the statement can be made with positiveness that the transference relations of these tri-ionic salts afford no indication of the presence of intermediate ions; but whether this is due to the non existence of such ions or to the fact that they have a conductance of such magnitude as not to influence the transference cannot be definitely stated.

8. Summary.

In this paper have been described transference experiments with 0.03 and 0.1 normal solutions of thallous sulphate and lead nitrate at 25°. The cation transference numbers found for the thallous salt are **0.479** at 0.03, and **0.476** at 0.1 normal, and for the lead salt **0.487** at both concentrations. The changes in content at both electrodes and in the middle portions have been determind, thus fixing the limit of error in the results, which can hardly exceed ±0.003, or about 0.5 per cent. The transference number at zero concentration as calculated from Kohlrausch's extrapolated values of the equivalent conductances of the separate ions is 0.489 for thallous sulphate and 0.503 for lead nitrate; thus 2.5 to 3.2 per cent. higher than the values found by direct measurement at 0.03-0.10 normal. Whether this change of the transference number with the concentration is real, is uncertain. Even if real, it is small, and lies in the case of thallous sulphate in the direction probably required by the presence of the intermediate ion; in the case of lead nitrate, in the opposit direction. The theoretical bearing of the results is discussed in the last two paragraphs of the preceding section. Taking also into consideration other accurate transference values for tri-ionic salts previously determined, it has been there shown that transference experiments make necessary one of two alternative conclusions: either the intermediate ion is not formed in any considerable proportion by the dissociation of tri-ionic salts up to moderate concentrations (0.1 to 0.2 normal), or else, if it is formed, its equivalent conductance has a definit value of such magnitude that the transference number is independent of its concentration.

---

[1] A. A. Noyes, *Ibid.*, 36, 79 (1901).

[2] Almost all the other tri ionic salts that have been accurately investigated are halides, the transference numbers of which as a rule change considerably with the concentration in a direction opposite to that which the presence of the intermediate ion would require, an effect which is not improbably due to the presence of complex anions. The existing data will be more fully considered with reference to the question here under discussion in a critical review of the results of transference experiments now under preparation.

THE CHARACTER OF SILVER DEPOSITS FROM VARIOUS ELECTROLYTES.

BY JOSIAH SIMPSON HUGHES[1] AND JAMES R. WITHROW

Received September 27, 1910.

In some work previously undertaken by one of us it became of interest to know the conditions which would give silver deposits of various properties or characteristics The discussion of this general subject by Bancroft[2] is of great assistance in indicating the variations of conditions which favor satisfactory deposition. The influence of each particular electrolyte on these conditions and the minor details of the deposit characteristics is a matter for experimentation. In this connection Snowdon[3] has gone thoroughly into the deposition of silver from nitric acid and potassium cyanide, using the rotating cathode. Other electrolytes have been used from time to time, especially in electroanalysis.

It was thought therefore that a repetition of some of the earlier work done on the electrolytic determination of silver would not only be helpful in the direction desired but would also be of interest from an analytical view point. The results included here give the outcome of some of these experiments, together with a summary of a series of trials made with new electrolytes.

The same dish cathodes were used that were employed in the work on copper.[4] The anode also was the same except that the diameter of the spiral was 5 cm. in the present case. The current was supplied by storage cells and was measured by Weston, Model 57, switchboard instruments. The ammeter had a range of one ampere and the scale was divided into hundredths. The voltmeter had a range of six volts and the scale was divided into twentieths. All readings given herein are direct instrument readings and are not referred to the "normal density."

---

[4] THIS JOURNAL, **30**, 381.

During electrolysis the anode was held 2 cm. above the bottom of the dish so that the distance from all parts of the cathode was nearly equal. The total dilution was always 125 cc., giving an estimated effective cathode area of 110 sq. cm. The time factor in the table is not of much importance, because in many cases the experiment ran all night and the silver was doubtless all out some time before the electrolysis was stopped. Sufficient silver nitrate solution was taken in each experiment to give the amount of silver indicated in the table as being present. Ammonium sulphide was used to test the end points. The following is a list of the liquid reagents used, together with their specific gravity in each case: Nitric acid, 1.42; ammonium hydroxide, 0.90; sulphuric acid, 1.84; perchloric acid, 1.12; and hydrofluosilicic acid, 1.06. Normal NaOH solution was used for this reagent. The deposits were washed and dried in the usual manner[1] before weighing. All data here given were obtained without agitating the electrolyte.

Since the early workers gave very few details of their work it is impossible to repeat it exactly. About all one can do in many cases is merely to use the same electrolyte and often the concentration of that is not known.

The first table gives the results obtained in the quantitative examination of electrolytes hitherto in use for various purposes.

The experiments with the nitric acid electrolyte showed that dense deposits cannot be obtained if the voltage is too high. When the voltage was kept lower, however, the deposits were good and of a crystallin nature. This is in agreement with the work of Kuster and von Steinwehr[2] with this electrolyte. Although sponginess is entirely avoided when the voltage is kept below 1.4 volts, yet the silver is deposited so slowly that there is a tendency for the crystals to grow large and become easily detached. Dense adherent deposits can be obtained without much difficulty, however, if the rotating anode is used. With stationary electrodes it was impossible to set the voltage at 1.3 volts, for instance, and expect it to remain there, for with this electrolyte especially it soon begins to rise and thereby passes the point at which discoloration and sponginess appear on the cathode. If the voltage was kept below 1.35 the deposit was smooth and white, finally becoming visibly crystallin. If after such a deposit is well under way, the voltage is raised to 1.5–1.8 volts, the deposit almost instantly darkens and then becomes spongy. If now the voltage is again lowered to 1.3 volts, there is a flash of white as the whole turns this color without even apparently affecting the de-

posit in any other way than color. Even the most delicate cauliflower-like effect of some spongy deposits is merely changed from dark (even black) to spotless white. This change is so closely connected with the change in voltage that it suggests its possible utilization in detecting the maximum allowable voltage for useful deposition from electrolytes which show the phenomenon. Nothing further could be done with it, however, at this time.

With the higher voltage much hydrogen is liberated at the cathode. This obviously reduces the cathode area and in this way greatly increases the effective current density. Conditions of this kind would naturally be expected to give rise to poor metallic deposits.

Once upon reducing the voltage in the manner described above, the deposit soon became a mass of needles a half millimeter or more in length.

Then when the voltage was raised to 1.6 volts bubbles of gas collected at once between the needles and did not visibly disengage themselves. This so reduced the cathode surface that only the termination of the needles was the effective cathode. This was shown by the fact that the terminations became like jet and stood out in marked contrast on the white background. Reducing the volts to 1 3 changed these terminations at once to their original white color.

In order to study the black deposit, often obtained, a heavy one was secured. The voltage was then reduced to 1.2 volts. This caused the usual flash of white metallic silver which covered everything that was black just before. The current was then reversed without disturbing anything in the dish. The double layer deposit (as it appeared to be) was now the anode and it almost completely corroded off without changing from the color of the later deposit of silver. That is, the layer of black which was laid down first on the cathode never became visible on what was now the anode. Although this is not definit proof, it seems to indicate that the white flash is a real bleaching or change in color of the black silver itself.

In the work with nitric acid there was often a tendency toward the formation of the well-known black, crystallized deposit on the anode.

Beautiful silvery deposits, difficult to distinguish from the dish, were often obtained at first from the ammonium sulphate-ammonium hydroxide electrolyte. Some of these deposits were like burnished silver but as the deposits became heavier they became more velvet-like and as the voltage ran above 1 4 volts they darkened. Rarely, however, did they develop sponginess as rapidly or to the same extent as those from nitric acid.

Number 9 started well but later became spongy. The 10th result and the beginning of number 9 show the favorable effect of lower voltage than was used at first. Experiments 11 to 16, inclusive, give in each case darkened deposits of varying intensity of shade. All of them were made with higher voltage. Some of them were run at elevated temperature but without any appreciable effect other than the usual corresponding shortening of the time necessary for complete precipitation. The weights of the deposits also in all cases with this electrolyte were high except when the pressure was kept below 1.4 volts. This is in agreement with the experience of Krutwig,[1] who proposed this electrolyte.

On a few occasions, when only a small amount of ammonium hydroxide was used with the ammonium sulphate electrolyte, the first layers of silver which came down were purple in color, changing in places to a deep blue color. This calls to mind at once the blue form of silver made by

---

[1] *Ber.*, 15, 1262.

Carey Lea years ago. Snowdon[1] seems to have encountered this under other circumstances. The deposits here mentioned were not as uniform as Snowdon obtained when he used a colloidal addition agent. None of the deposits made at 1.5 volts were adherent The simultaneous darkening of the deposits and excess weight might be explained by the assumption of the formation of silver sulphide at the cathode. The function of the ammonium hydroxide appears to be the prevention of anodic deposit formation. When the amount of this reagent was lessened there was an anodic deposit as was found in experiments 8 and 14.

When ammonium sulphate was employed in the absence of ammonium hydroxide there very quickly formed on the anode a heavy black deposit which shone at times like polished graphite This deposit was at once dispelled upon the addition of a few drops of ammonium hydroxide.

In experiment 17 sufficient ammonium hydroxide was added to dissolve the precipitate first formed. When the ammoniacal phosphate and pyrophosphate electrolytes were used the deposits were crystallin in every case. Here also, however, too high voltage causes sponginess.

The potassium cyanide used in the experiments with this electrolyte was the commercial grade Most of the deposits from this electrolyte were white and good. The quantitative results seem to be best when an elevated temperature is used The dark effect which appeared in the electrolyte around the anode seemed to migrate to the cathode. There was always a slight black residue left after dissolving the silver deposit in nitric acid This substance resembled carbon and disappeared when the dish was heated but was not identified

The final table shows in a compact way the general results obtained when using other electrolytes than those mentioned in the literature. The experiments are all qualitative and were made to determin the character of the resulting deposits. The fluosilicic acid electrolyte is not new, although given in the final table. It has been used by Jarvis and Kern in their study of the effect of addition agents on the density and coherence of silver deposits[2] This article is only accessible to us through abstract.[3] The abstract gives no information, however, concerning the nature of the deposits obtained from this particular electrolyte. We only examined the electrolyte qualitatively and hence put it with the other qualitative results.

The deposits from sulphuric acid and glycerol were so coarsely crystallin as to be non adherent. The sodium and ammonium hydroxide mixture gave a fairly adherent deposit. The deposit in experiment 8 was not so coarse as in the preceding experiments. The fluosilicic acid seems to be the most satisfactory of any of the last electrolytes tried. At 50° there was no oxide on the anode, and the deposit did not become spongy at as low a voltage as in the other cases.

13	H_2SiF_6	5 cc.	0.2	1.7	50°		Spongy

Summary.

1. The general characteristics are described of the silver deposits from a variety of electrolytes.

2. With all the electrolytes tried except cyanide·ly, hc is a point at about 1.4 volts beyond which, with the conditions 'nt a used, spongy deposits will result. With cyanide this point is much higher.

3. Satisfactory conditions have been tabulated for the quantitative precipitation of silver from several electrolytes.

4. Several other electrolytes have been tried which seem worthy of further investigation.

COLUMBUS, OHIO.

RATE OF HYDRATION OF PYROPHOSPHORIC ACID. A CORRECTION.

By G. A. ABBOTT.

Through the kindness of Dr. J. M. Bell, of the University of North Carolina, my attention has recently been called to the fact that the experimental data given in Table IV of my article on the Rate of Hydration of Pyrophosphoric Acid[1] are not consistent with the statement in the text that the specific conductance of a mixture of the pyro and ortho acids is a linear function of its composition. Through a regrettable error in copying, the wrong data were included in the table referred to, and it is the purpose of this note to present the correct ones. The following table should be substituted for that given in the article:

---

[1] THIS JOURNAL, 31, 766 (1909).

TABLE IV.—SPECIFIC CONDUCTANCE (L) $\times 10^6$ OF MIXTURES OF PYRO- AND ORTHO-PHOSPHORIC ACIDS AT 18°.

At wts. P per liter.	Per cent P as ortho acid.	100	75	50	25	0
	Per cent. P as pyro acid.	0	25	50	75	100
0 1	Found	9650	11640	13650	15610	17690
	Calculated	..	11660	13670	15680	. .
0 05	Found	6135	6992	7874	8726	9622
	Calculated..	. .	7007	7878	8750	....
0.01	Found	2030	2154	2275	2388	2517
	Calculated	. ..	2152	2274	2395	.. .

The degree of the divergence from a linear relation between conductance and composition will be seen by comparing the found values with the calculated ones given in the rows just beneath them. These calculated values were obtained by the expression $xL_o + (1 - x)L_p$, where x represents the fraction of the phosphorus present in the mixture as ortho acid, L_o the conductance of the pure ortho acid, and L_p that of the pure pyro acid. It will be seen that the difference is largest in the case of the mixtures with 25 per cent. ortho acid, but that even in this case it averages only about 0 4 per cent.

This opportunity may be also utilized for correcting the following typographical errors in the article on The Ionization Relations of Ortho- and Pyrophosphoric Acids and their Sodium Salts, by Abbott and Bray:[1]

On page 742, line 19, insert K_B in the denominator of the expression for K_3.

On page 751, line 14, read 353 8 instead of 358 8.

On page 751, last two lines, read K'_1, for K'_2 and K'_2 for K'_1.

On page 753, in Fig. 2, read $Na_4P_2O_7$ in place of $Na_4P_4O_3$.

On page 762, in Table XXIII, read $H_2PO_4^-$ in place of HPO_4^- and $H_3P_2O_7^-$ in place of $HP_2O_7^-$.

A REVISION OF THE ATOMIC WEIGHT OF CALCIUM. I. ANALYSIS OF CALCIUM BROMIDE.

BY THEODORE W. RICHARDS AND OTTO HÖNIGSCHMID.

Received October 24, 1910.

Introduction.

During the last fifty years the atomic weight of calcium has been repeatedly investigated, but most of the investigations have not led to very favorable results. According to the opinion of Brauner,[1] one of the most competent of modern critics, only two of the modern researches, namely that by one of the present authors[2] and that by Hinrichsen,[3] are to be considered as free from serious error.

---

[1] THIS JOURNAL, 31, 729 (1909).

The investigation of the atomic weight of calcium was undertaken at Harvard about fifteen years ago, and preliminary determinations were made upon the relation of calcium chloride to silver chloride, resulting in a value for the atomic weight of calcium of 40.085, if silver and chlorine are given the values of 107.88 and 35.457, respectively. Hinrichsen, on the other hand, without knowledge of the Harvard work, used the old method of converting calcium carbonate to oxide, obtaining therefrom a much higher value, 40.139. Before Stas' atomic weight of silver (107.93) was found to be in error, the two results seemed to be fairly consistent, but with modern values the difference is considerable.

This difference between the two values suggests the importance of a new determination of this important constant, especially because each of the earlier investigators had used only one method. We accordingly began the investigation with the analysis of calcium bromide, and determined not only the amount of silver needed to precipitate the bromine, but also the amount of silver bromide obtained. As will be seen, the results supported rather the earlier Harvard work than the higher value of Hinrichsen, The outcome of this investigation of the bromide (Ca = 40.070) is slightly lower even than the value obtained from the chloride. Further work upon the chloride has already been begun and it is hoped that further results upon this subject also may be communicated in the near future.

It is a pleasure to express our obligation to the Carnegie Institute of Washington for generous pecuniary assistance, without which much of the apparatus necessary in this investigation could not have been procured.

Preparation of Materials.

During the earlier work upon the atomic weight of calcium, undertaken fifteen years ago, certain tests were made concerning the adequacy of the purification of calcium nitrate from magnesium and from allied elements.

A concentrated calcium nitrate solution containing some magnesium was treated with milk of lime, and the solution was allowed to stand for three days, being shaken repeatedly. One-tenth liter of the supernatant solution, containing about 25 grams of calcium nitrate, was diluted to 0.3 liter and made strongly alkaline with ammonia. Fifty grams of ammonium chloride were added and the calcium was wholly precipitated hot by excess of ammonium oxalate. No magnesium whatever could be found by the usual phosphate test in the filtrate, showing that the treatment with lime eliminates most of the magnesium; but the test does not conclusively prove that all the impurity is removed, for a trace might have been carried down with the oxalate, and thus have escaped detection. It will presently be shown that the crystallization of the nitrate is an effective means of removing the last traces of magnesium, if any such are present.

Turning now to the removal of barium and strontium from the calcium precipitations, an effort to accomplish this by means of sulphuric acid may first be described First a 20 per cent. solution of calcium nitrate was treated with a small quantity of sulphuric acid, enough to produce a small precipitate, and this precipitate was tested carefully for strontium and barium with negative results The successive addition, three times, of small further weights of sulphuric acid likewise gave no test for strontium or barium, in spite of the fact that the solution was known to contain a precipitable amount of strontium and a trace of barium.

There is indeed nothing surprising in this observation; it is owing to the fact that the solubility of any electrolyte in a solvent containing different ions is so much increased that the last traces cannot be eliminated by any ordinary process of precipitation. In order to eliminate the impurity, the desired substance, not the impurity, must be separated out.

Abandoning now these methods of purification, which rest upon a wrong principle, the following test was made of the recrystallization of calcium nitrate. To 200 grams of a fairly pure sample of calcium nitrate were added 2 grams each of barium, strontium and magnesium nitrates. The mixed solution was then concentrated and about three fourths of the calcium nitrate was crystallized from it by cooling. In the mother liquor strong tests for barium, strontium and magnesium could be obtained, while in the crystals indications of these impurities were much feebler, although still unquestionable. The crystals were dissolved and recrystallized twice. The third mother liquor gave no test whatever for magnesium by means of phosphate solutions in the usual way, or for strontium in the spectroscope, but gave a very faint precipitate with sulphuric acid, showing the presence of barium. The crystals contained much less barium.

It is clear that when the calcium nitrate is recrystallized, these other contaminating nitrates tend strongly toward the mother liquor. Hence it is not surprising that the next crystallization, the fourth, yielded crystals in which no impurity whatsoever could be found by any ordinary tests. If four crystallizations can accomplish this, when as much as three per cent. of impurity is present, it is clear that when the initial purity is greater, the product must be exceedingly pure, especially upon still further crystallization; for in the distribution between the crystals and mother liquor, each mother liquor tends to hold the greater part of the contaminating substance. Hence both in the earlier investigation and in the present one, as well as in any other investigation in which pure calcium salts are needed, it was our invariable practice to purify the material through the recrystallization of the nitrate.

Calcium Nitrate.—For the present investigation 2 kilograms of a good quality of marble were dissolved in a small excess of the purest commercial nitric acid and the solution was boiled with chlorine water in order to oxidize the iron—an end effected only very slowly by dilute nitric acid. Pure milk of lime was then added in slight excess in order to precipitate the iron and magnesium. The clear filtrate, after the separation of the impurities in solid form, was evaporated to crystallization; and the nitrate was crystallized five times in porcelain vessels and yet five times more in platinum vessels. Each crop of crystals was thoroughly freed from mother liquor by means of a centrifugal machine, at first of porcelain, afterwards of platinum, so that the final crystals came in contact with nothing but the noble metal.

A second specimen of calcium nitrate was prepared from pure calcium carbonate which had been precipitated from nitrate prepared in the manner above described, but with fewer crystallizations. The carbonate was precipitated by means of ammonium carbonate and was washed by repeated decantations and centrifugal action. It was finally dissolved in the purest nitric acid and the nitrate was crystallized four times from the purest water in platinum vessels and whirled in the platinum centrifuge. This calcium nitrate (Sample 2) was used as the basis for the preparation of most of the calcium bromide.

Calcium Carbonate.—From the solution of calcium nitrate thus prepared the carbonate was precipitated by means of very pure ammonium carbonate. For the preparation of this substance in a state of sufficient purity, the purest ammonium carbonate of commerce was distilled with water by means of a platinum cooler. The distillate was collected in a platinum flask containing thrice distilled water, cooled with ice outside. The precipitation of the calcium carbonate was conducted at 100° in a platinum vessel and the precipitate was repeatedly washed with the purest water and centrifugally freed from adhering wash water. The pure carbonate was preserved in a platinum dish in a desiccator containing lime made from pure marble, in order to protect it from the access of impurity from glass and from the atmosphere of the laboratory. It is needless to say that carbonates are especially liable to be contaminated by traces of any strong acid in their neighborhood.

Hydrobromic Acid.—This acid, which was used in very large amounts, was made by the catalytic action of hot platinum on the mixture of hydrogen and bromine vapor. The bromine was prepared from a mixture of pure bromide and bromate by means of sulphuric acid and was still further purified before it was united with the hydrogen.

The bromide had been made from bromate, and this had been many times recrystallized in order to free it from traces of chloride and chlorate. The bromate, and therefore the bromide, made from it, were almost, if not quite, free from iodine, as far as any ordinary test could indicate.[1]

The purest concentrated sulphuric acid of the laboratory was used for the decomposition of the mixed bromate and bromide, and the reaction was carried out in a flask, into which was ground a glass stopper containing a drop funnel and the tube for leading off the bromine vapor. The flask was partly filled with a cold saturated solution of potassium bromide, and the calculated weight of the bromate was added in solid condition. The exit tube was led into another flask partially filled with the purest water and packed in ice; and the reaction was carried out by the gradual dropping in of the acid and gentle warming. There was no difficulty in regulating the speed of the reaction in this way. In each operation only about 50 grams of bromine were prepared, but as this was repeated twenty times, about a kilogram was finally obtained. The bromine thus prepared was purified by solution in a concentrated solution of calcium bromide (made from the same bromine and pure halogen-free lime, according to Stas' method) and the pure bromine was finally once more distilled.

From this bromine, hydrobromic acid was made, as already stated, through direct union of the components with catalytic acceleration by means of platinum asbestos. The hydrogen was prepared through the action of so-called "hydrone" (an alloy of lead and sodium) upon water. The gas was passed through a drying apparatus filled with stick potash, next through a gas-washing bottle filled with the pure bromine, and finally into a Jena hard-glass tube in which platinum asbestos was heated by means of an electric furnace to about 400°. The hydrobromic acid was led into pure water and cooled by ice. The dilute solution of hydrobromic acid thus made always contained an excess of bromine; upon distillation, this bromine, together with any possible traces of iodine which might have been present, came over first and was discarded. The main portion of the acid was distilled and condensed by means of a quartz cooler, and the distillate was collected in a quartz flask.

---

[1] These materials were both presented to us by Mr. H. H. Dow, of the Midland Chemical Company, Indiana. We take pleasure in acknowledging our indebtedness to him for his generosity and for the trouble which he took in conducting very carefully the preliminary purification of large amounts of both substances.

Calcium Bromide.—All the calcium bromide used in the investigation was prepared with hydrobromic acid made in this fashion. The pure specimens of calcium carbonate were in the first place heated in an electric oven until wholly dry and free from traces of ammonium salts which always cling to carbonate prepared as this had been. Even if traces of the ammonium salts remained after this treatment, they would not have been harmful; for they must have been wholly volatilized at the high temperature to which the calcium bromide was subsequently heated. Calcium carbonate thus dried was added in small portions to the pure acid in the quartz flask as long as evolution of gas continued. The solution was then slightly acidified, transferred to a quartz dish and concentrated upon an electric stove. The solution always became yellow, because traces of calcium nitrate (held by the calcium carbonate) invariably set free corresponding traces of bromine during the evaporation.

In these quartz vessels the bromide was recrystallized; thus from beginning to end neither the factors nor the product of the reaction came into contact with glass. The first specimen of calcium bromide was nine times crystallized, during which process of course the greater part of the salt found its way into the mother liquors, and only substance enough for two analyses (Nos. 16 and 17) was obtained. The substance from the mother liquors, after four recrystallizations, was used for preliminary determinations.

A second preparation of bromide was made out of the second preparation of nitrate in a similar manner except that the bromide was crystallized only four times. This preparation served for all the final analyses with the exception of the two mentioned above.

Before the final crystallization in each case the solution was filtered through a platinum Gooch-Munroe crucible. This is important, for in spite of the greatest possible care traces of dust find their way inevitably into the solution and are held by the crystals, appearing in the fused calcium bromide at the end as minute black specks of carbon. When the salt has been filtered just before the last crystallization, such undesirable irregularities are absent. The efficacy of the process of purification was in every case greatly increased by means of the centrifugal drying of the crystals with the help of a centrifuge composed of swinging platinum funnels driven at a high speed by an electric motor. All the operations of transference and evaporation were effected inside of a glass house erected on the laboratory desk, composed of large glass plates held together by a light framework of wood. These plates had been carefully rounded on the edges with a file and protected by split rubber tube, so as to protect the edges and prevent the rubbing off of small particles of glass. An electric stove with a quartz top provided a source of heat for all these operations.

Silver.—The silver was prepared in a manner essentially similar to that used in other recent investigations in Harvard University. It was many times recrystallized as the nitrate, precipitated as pure silver by means of ammonium formate, and fused on boats of pure lime in a stream of pure dry hydrogen. For further particulars previous papers from this laboratory should be consulted.[1]

The Drying and Melting of Calcium Bromide, and the Neutrality of Its Solution.

The salt crystallizes with six molecules of water of crystallization, and dissolves in this water of crystallization at about 38°. As in the case of other concentrated solutions, of similar kinds, the quantitative expulsion of the water from this solution is a difficult matter. Accordingly, in order to dry the salt, the method was adopted which had been used successfully in the earlier analyses of calcium chloride by one of us. The salt was in the first place dried in a desiccator warmed to a temperature just below the "melting point" of the crystallized salt, pure lime being used as the desiccating agent. The water then escapes with considerable rapidity from the crystals, leaving a quantity of effloresced material whose melting point is above 200°. The evaporation of the water from the crystals is of course much hastened by having the vacuum as perfect as possible; accordingly the vacuum desiccator was thoroughly exhausted at a low temperature by means of a Geryk pump. The salt itself was placed in a flat platinum dish. After remaining about eight days in the desiccator, the temperature in the thermostat containing this apparatus could be raised to 50 or 60°, and after eight days more the dehydration had proceeded so far that the water could be all driven off at a much higher temperature without danger of partial melting and the projection of drops of the solution.

In order to eliminate the last traces of water, the salt was melted as usual in a current of hydrogen mixed with hydrobromic acid. This last substance is necessary to prevent the partial decomposition of the salt by the remaining trace of water at a high temperature. The temperature was raised very slowly so that as much water as possible should be driven off from the salt while it was still in a solid condition, and only at the every end was the temperature raised to the melting point at a red heat. The heating was conducted electrically by means of a ribbon of an alloy of nickel and chromium wound directly around the quartz tube which contained the platinum boat holding the calcium bromide to be melted. The progress of the fusion could be watched through the spaces between the ribbon. For twenty minutes the calcium bromide was kept in a fused condition at a medium red heat; and by means of light rapping on the tube the mobile liquid was freed as much as possible from bubbles of gas. When this heating had been finished the hydrogen and hydrobromic acid were shut off, and pure nitrogen was led into the tube, at the same time lowering the temperature to about 400°. After all trace of hydrobromic acid had been driven out, the salt was allowed to cool in a stream of nitrogen, and finally this gas was replaced by pure air. The succession of gases was provided by means of suitably arranged purifiers, all connected by glass stopcocks in a method which has been described in previous communications. The quartz tube was attached to the familiar Harvard "bottling apparatus" by means of which the pure anhydrous bromide was enclosed in a weighing tube in an atmosphere of pure air, and after it had become completely cooled this weighing tube was taken out and placed in a desiccator for at least five hours near the balance by means of which it was to be weighed. Successive weighings of the boat and bottle never differed more than 0.02 milligram. The empty boat and weighing bottle were weighed both before and after the determination. For this purpose they received precisely the same treatment as during an analysis, the boat being ignited in the bottling apparatus, and prepared for weighing just as if it contained calcium bromide. The similarity of treatment affords the best means of avoiding constant errors. That the apparatus served its purpose is clear from the fact that in two cases wherein specimens of melted and weighed bromide were once more melted and weighed, no change exceeding a few hundredths of a milligram was to be observed. The loss of weight of the boat during fusion was never over one-twentieth of a milligram, and sometimes amounted to nothing at all.

---

[1] See especially Richards and Wells, THIS JOURNAL, **27**, 472 (1905). *Pub. Carnegie Inst.*, **28**, 16 (1905). *Z. anorg. Chem.*, **46**, 70 (1905). "Experimentelle Untersuchungen," T. W. Richards [Hamburg, 1909], p. 703.

The bromide was dissolved in water in a large Erlenmeyer flask capable of holding three liters, with a ground stopper. The details were similar to those in the case of lithium chloride,[1] except that the testing for neutrality was somewhat different, because calcium bromide is decidedly a less stable salt than most of the other halides which have been studied in this laboratory, and therefore is less easy to obtain in a state of perfect neutrality. When heated with either air or with water, it is certain to lose some bromine and become alkaline. On the other hand, when heated with hydrobromic acid, a trace of this gas is dissolved. This trace is indeed quickly liberated on further fusion in nitrogen, but if the nitrogen is not absolutely pure, there is danger of overstepping the mark and making the salt slightly alkaline in this process. Therefore every sample of calcium bromide must be carefully tested in order to be sure of its perfect neutrality; and because the salt is slightly hydrolyzed in aqueous solution, the only satisfactory method of testing it is to compare the solution of the fused salt with a solution of the same concentration made from the purest calcium bromide many times recrystallized. The latter, if prepared with adequate care, is presumably neutral, for there is no evidence that either hydrobromic acid or lime tend to go into the crystals to any perceptible extent. In order, therefore, to determine the deviation from neutrality of the fused calcium bromide, it was dissolved in a small amount of water, and to it was added 10 cc. of a saturated aqueous solution of the slightly soluble methyl red, the only indicator which seemed to serve well for this purpose. To the same volume of a solution containing the crystallized salt, assumed to be neutral, was added a like volume of the solution of methyl red, and the colors of the two solutions were compared. When the colors of the two solutions appeared identical, it was reasonable to infer that the fused salt was perfectly neutral. This occurred in two out of the twelve cases. In most cases the fused salt was found to be either slightly alkaline or slightly acid, but two or three drops of the corresponding hundredth normal solution were enough to restore perfect neutralization, except in one case when five drops were required. The appropriate corrections were of course made in the weighings of fused calcium bromide to eliminate the errors which would otherwise have existed in the results because of this lack of neutrality. The absence of such corrections was one of the chief reasons why the ten preliminary results, not worthy of recording here, varied among themselves by amounts distinctly greater than those to be noted in the final results, recorded later.

---

[1] Richards and Willard, THIS JOURNAL, 32, 4 (1910). *Pub. Carnegie Inst. of Washington*, 125.

After the testing for neutrality, the solution was diluted with a liter of the purest water, and the boat was removed by means of a platinum wire, and very thoroughly washed with all possible care. The analysis of the bromide was then carried out by either one of the two usual methods, namely, either the determination of the exact amount of silver equivalent to the calcium present, or the weighing of the precipitated silver bromide. These two processes were never executed in the same experiment in either of the final series, because each can be done more satisfactorily if attention is concentrated upon it alone.

Balance and Weights.—The weighings were made upon a very good balance of Prussian manufacture which had been thoroughly tested and was easily sensitive to 0.01 mg. The gilded brass weights were standardized according to the method usually employed in this laboratory and were often further tested during the progress of the research. As usual, all readings were made by substitution, the substituted tare being an object similar in all respects to that which was being weighed.

It was necessary to determine anew the specific gravity of calcium bromide, because the published values of this constant are highly discrepant among themselves, differing to an extent sufficient to influence appreciably the calculation of the true weight of the substance. This determination was carried out in a pycnometer for hygroscopic solids described by Baxter.[1] Toluene was used as a fluid to be displaced. The sample had been distilled over sodium and was found to have at 25° a density of 0 8605 as the mean of three trials. With this apparatus 2 09625 grams of calcium bromide displaced 0 5378 gram of toluene and 2.974 grams of calcium bromide displaced 0.7629 gram of toluene, the readings being reduced to the vacuum standard. These two determinations give as the specific gravity of calcium bromide the values 3.354 and 3.353, respectively—results essentially identical.

The vacuum corrections to be applied to silver, silver bromide and calcium bromide, when the readings were conducted in air at normal pressure and at 20°, were taken as —0.030 mg., +0.041 mg. and +0 218 mg., respectively, the specific gravity of the brass weights being 8.3. The small changes due to changing pressure and temperature were almost always negligible with these dense substances.

The Determination of the Silver Corresponding to Calcium Bromide.

A weight of purest silver as nearly as possible equivalent to each portion of carefully weighed bromide (as found in the preliminary experiments) was dissolved in nitric acid in a large flask with bulbs to prevent the escape of spray; and the solution was warmed until the nitrous vapors had been wholly driven out. The solution was then diluted so that it contained not more than 10 grams of silver in a liter of water. Every drop of solution was then added in the red light of the dark room to the corresponding bromide solution, little by little, the latter liquid being kept in continual motion. The flask which had contained the silver was of course washed with the greatest care, and the last washings were tested in a nephelometer in order to be sure that every trace of silver had been removed. The mixture had in every case, after precipitation, a volume of about 2.5 liters. It was at first only gently shaken in order to promote complete precipitation without causing the precipitate to cohere into impenetrable balls; and the mixture in this state was left for twenty-four hours in the dark room covered with a black cloth in order that complete equilibrium might establish itself between the precipitate and the solution. In this way opportunity is given for the washing out of any excess of either reagent which may be occluded by the spongy precipitate. When this is accomplished, the mixture is violently shaken for twenty minutes, the flask being closely stoppered. Under this treatment the precipitate coheres satisfactorily and deposits itself after short standing so completely that the small particles which cling to the flask above the level of the liquid can easily be washed down into the flask by tilting the latter backwards and forwards, thus causing the clear liquid to wash every portion of the neck.

---

[1] Baxter and Hines, *Am. Chem. J.*, 31, 220 (1904).

During this whole time the flask was never opened and especial care was taken that no traces of the precipitate should be held in the control space between the lower end of the stopper and the wall of the flask.

The mixture was now ready for filtration. In order to prevent the ejection of drops of liquid on the removal of the stopper, the air in the flask had been slightly warmed by means of the hands before this stopper had been applied in the first place, so that on opening the flask for filtration air was drawn in and not expelled. Cooling the flask with cold water before opening increased this effect. Upon the removal of the stopper, the neck of the flask and stopper were carefully washed with the purest water; and when the solution had been mixed by two or three rotations of the flask, two samples of the clear mother liquor were taken out and placed in two test tubes. To one was added a solution of a milligram of silver; to the other a corresponding amount of potassium bromide; and both were stirred by suitable bent rods. The comparison of the two tubes in the nephelometer enabled one to see at once whether the bromide or the silver was in excess, and it was easy to be sure of an amount corresponding to 0.05 milligram of silver or of bromide in a liter of the solution. If one or the other was found to be deficient, the corresponding amount was added to the whole mass of the solution, and after new shaking and standing another trial in the nephelometer was made. This process was repeated until the nephelometer showed the end point of the reaction, both tubes exhibiting like opalescence. Incidentally it may be noted once more that the liquids in the nephelometer tubes must be allowed to stand for at least 1.5 to 2 hours after they have been precipitated, otherwise the precipitates do not attain constancy. It is essential that during this time, indeed as promptly as possible after they have been filled, the tubes should be covered with glass caps made of rings sealed to round plates of plane optical glass in order to prevent the access of dust and the resulting serious errors in the outcome. The nephelometer can easily detect 1/3000 of a milligram of chlorine, and a single mote of dust may contain this amount.

The following table gives the results of the last six analyses, carried out in this way. It is worthy of note that these analyses are all consecutive ones, the thirteenth not having been brought to a conclusion on account of a mistake in weighing the silver. No finished analysis was rejected:

THE RATIO OF CALCIUM BROMIDE TO SILVER.

No. of exp.	Weight of calcium bromide in vacuum	Weight of silver in vacuum.	Ratio $CaBr_2:2Ag$.	Atomic weight of calcium, Ag = 107.88.
11	4.20860	4.54252	0.926490	40.068
12	4.58644	4.95025	0.926507	40.071
14	5.34866	5.77301	0.926491	40.068
15	7.23724	7.81126	0.926514	40.073
16	4.67673	5.04779	0.926491	40.068
17	7.41636	8.00455	0.926518	40.074
	Sum, 33.47403	36.12938	Average, 0.926502	40.0703

From these six analyses it would appear that the atomic weight of calcium is to be taken as 40.070, if silver is taken as 107.88 (the present international value). The extremes 40.068 and 40.074 deviate but slightly from the mean, and the so-called "probable error" of the average is only 0.0007. The series is as concordant as could reasonably be expected, and except for one possibly insignificant fact would go entirely unchallenged. This fact is the hitherto unexplained circumstance that the experiments where larger quantities of material were used gave slightly higher results than those where smaller quantities were used. The same circumstance is to be noted in the second series of results to be recorded shortly. The agreement of the verdict of these two series may be merely a coincidence, and in any case the deviation is so slight as to cause uncertainty only in the third decimal place of the atomic weight. If, as is probable, the results with the larger quantities are somewhat more accurate, the value 40.07 may be slightly too low; but the true value is not likely to be as high as 40.08.[1]

A more reassuring conclusion may be drawn from another aspect of the results. It is satisfactory that the two different preparations of bromide gave results essentially identical. The specimen recrystallized nine times, which was used in analyses 16 and 17, gave as the mean value 40.071, whereas that which had been recrystallized four times (used in analyses 11 to 15) gave 40.070, a result essentially identical. This seems to indicate that both preparations were really pure; for it is not probable that if impurities had been present a product crystallized nine times would have shown precisely the same result as one crystallized only four times, especially when one considers that the recrystallization was carried out with the help of an energetic centrifuge.

The Determination of the Relation of Calcium Bromide to Silver Bromide.

The method of precipitation of silver bromide for weighing was essentially similar to the method used in previous cases in this laboratory. Only a very slight excess of silver was used in precipitating in order to avoid occlusion of silver nitrate. The precipitation was accomplished in the manner just described and a platinum Gooch-Munroe crucible was used for filtration.[1] The precipitate was first washed seven to ten times by decantation with small quantities of the purest water, and finally was washed upon the filtering crucible by means of a jet driven by hydrostatic pressure. Both mother liquor and wash water were preserved separately and carefully tested in the nephelometer for the traces of bromide which they might contain. The mother liquor rarely contained a trace of bromide, the wash water usually about 0.2 milligram per liter. The filtration was conducted under a glass roof, which served to protect the crucible from dust. The flask in which the precipitation had been conducted was finally washed with a small quantity of the purest freshly distilled, concentrated ammonia, in order to dissolve any trace of silver bromide which might have escaped transference into the crucible. After neutralization with the purest nitric acid this mixture too was tested in the nephelometer with excess of silver solution. In making the nephelometric tests, comparison was made in each case with a standard prepared in precisely the same way.

As usual, the dry precipitate, after having been weighed, was transferred to a small porcelain crucible, weighed again, cautiously heated, and weighed for the third time. The fused mass, which was distributed over the inside surface of the crucible by gently rotating the crucible while inclined at a small angle, was a clear yellow upon cooling and gave evidence of being very pure. The loss during melting was never more than 0.004 per cent. and was usually much less.

These rather complicated processes are subject to somewhat greater possibilities of error than the much simpler comparison with silver, but the agreement of the results was, as a matter of fact, about the same as before. The six analyses recorded in this table represent a series from which none is omitted. They were carried out after the necessary experience gained in preliminary determinations.

THE RATIO OF CALCIUM BROMIDE TO SILVER BROMIDE

No. of exp.	Weight of calcium bromide in vacuum.	Weight of silver bromide in vacuum.	Ratio $CaBr_2 \cdot 2AgBr$	Atomic weight of calcium AgBr = 187.796.
18	10.18591	19.13778	0.532241	40.073
19	7.92400	14.88810	0.532237	40.072
20	6.78048	12.73961	0.532236	40.072
21	6.45970	12.13702	0.532231	40.070
22	5.95390	11.18684	0.532225	40.067
23	5.15998	9.69513	0.532225	40.067
	Sum, 42.46397	79.78448	Average, 0.5322323	40.0702

A glance at this table shows that the figures recorded in it afford a complete confirmation of the results contained in the first table, although these were reached by a different road. Indeed the final averages (40.0702 and 40.0703) are almost precisely the same in the two cases, far within the almost equal "probable errors" (0.0007) of the two series. In the present case, as in the other, the greatest deviation from the mean is about 3 in the third decimal place of the atomic weight of calcium, or about 1 in 70,000 in the total weight of the calcium bromide; this seems to be about the limit of reasonable accuracy in such experimentation. The result, as in the other case, is probably to be regarded as a minimum value, and it seems fairly safe to conclude that the atomic weight of calcium is between 40.07 and 40.08.

---

[1] Richards and Mueller, *Z. anorg. Chem.*, **53**, 438 (1907); THIS JOURNAL, **29**, 651 (1907).

Obviously, because the two series give identical results, the atomic weight of bromine computed from the two average results is equal to that assumed in the calculation of each series, namely, 79.916, if silver is 107.88. This shows that the calcium bromide was free from chloride, and that the occlusion of other salts by the silver bromide must have been imperceptible.

We have already obtained some interesting confirmatory results with calcium chloride, which will soon be ready for publication, and hope to continue the study of this atomic weight and to settle such points as remain obscure.

Summary.

The results of this paper may be stated in a few words, as follows:

Methods for the preparation, dehydration, and melting of pure calcium bromide were devised.

Calcium bromide proved to be less stable on melting than the corresponding barium and strontium salts. By comparison with pure crystallized salt with the help of methyl red, the very slight deviations of the several specimens of melted bromide from exact neutrality were determined in their aqueous solutions.

The density of melted calcium bromide was found to be 3.353 at 25°.

33.47403 grams (in vacuum) of calcium bromide required 36.12938 grams (in vacuum) of silver for complete precipitation. Again, 42.46397 grams (in vacuum) of calcium bromide yielded 79 78448 grams (in vacuum) of silver bromide, each set of figures being the sum of the quantities used in six consecutive determinations. The two ratios give essentially the same value for the atomic weight of calcium, 40 070, if silver is taken as 107 88. The value becomes 40.066 if silver is taken as 107.87. This result is probably a minimum value; but it is improbable that the true one exceeds 40.08.

The investigation shows that the preliminary Harvard work yielded a value for the atomic weight of calcium much more probable than that found by the only other modern investigator.

A REVISION OF THE ATOMIC WEIGHTS OF SILVER AND IODINE.

[SECOND PAPER.]

THE RATIO OF SILVER TO IODINE.

BY GREGORY PAUL BAXTER

Received October 22, 1910

Introduction.

In a recent investigation upon the atomic weights of silver and iodine, Baxter and Tilley[1] determined the ratio between silver and iodine pentoxide to be 0 646230. Then, the ratio of silver to iodine having previously been found by Baxter[2] to be 0 849943, the per cent. of iodine in the pentoxide was calculated, and thence the atomic weights of iodine and silver. Since the results obtained in this way were unexpectedly low, 126.891 and 107 850 respectively, while several recent investigations, especially that of Richards and Willard[3] on the ratio of lithium chloride to lithium perchlorate, have shown the atomic weight of silver to be not far from 107 871, and since all known possible causes of error in the determination of the ratio of silver to iodine pentoxide were very carefully investigated, it was possible that the final results might have been influenced by an error in the ratio of silver to iodine. This error need be only very slight to explain the discrepancy, because a given percentage error in the ratio of silver to iodine produces one three times as large in the atomic weights of iodine and silver, but in the opposit direction.

In the determination of the ratio of silver to iodine[4] the preparation of silver iodide in every case formed one step in the procedure. The latter substance is, however, difficult to obtain in a pure condition on account of its strong tendency to occlude soluble silver salts. The difficulty was eliminated as far as was possible at the time, either by precipitation of the silver iodide in ammoniacal solution, or by precipitation at high dilution, these precautions having been shown by both Köthner and Aeuer[5] and Baxter[6] to be beneficial. The evidence obtained in the investigation upon iodine pentoxide indicates that even the pains taken in the early work upon the silver-iodine ratio to avoid occlusion by the silver iodide may not have been sufficient entirely to eliminate the difficulty, and hence that the above value of the silver-iodine ratio is too high. Furthermore, it is noticeable that many of the earlier results upon the silver-iodine ratio indicate a perceptibly lower value for the ratio than the one given above, while most of the possible errors would have tended to produce too high a result. Hence new experiments were instituted for the investigation of the silver-iodine ratio.

It seemed highly desirable in these new experiments to carry out the determination of the ratio of silver to iodine in as nearly as possible the same way as in the determination of the ratio of silver to pentoxide, and also to use material which had been purified in as nearly as possible the same way. Thus constant errors which might enter into the determination of the latter ratio would be likely to be compensated by similar errors in the determination of the former ratio.

The method, in brief, was as follows: Weighed quantities of iodine were reduced to hydriodic acid by a solution of hydrazine hydroxide. After considerable dilution the iodine was precipitated as silver iodide by a very dilute solution of silver nitrate containing a few tenths of a milligram excess of silver. The clear supernatant solution was carefully filtered and evaporated to small bulk, and the excess of silver was determined gravimetrically as silver iodide.

Purification of Materials.

Iodine.—Three specimens of iodine were employed. Sample 1 was made from iodic acid remaining from the research upon iodine pentoxide.[1] The iodic acid had been prepared by the action of the purest fuming nitric acid upon very pure iodine, in quartz vessels, and had been crystallized ten times from aqueous solution in a quartz dish.

A second specimen of iodic acid was made from potassium iodate in the following manner: Potassium permanganate was allowed to react with potassium iodide in concentrated hot solution. The products of this reaction are potassium iodate, potassium hydroxide and manganese dioxide. After the precipitated manganese dioxide had been separated from the solution by decantation and filtration, the solution was evaporated to crystallization, and the crystals were carefully separated from the mother liquor by centrifugal drainage. The mother liquor was several times evaporated until the greater part of the iodate had been recovered. A second portion of potassium iodate was made by allowing potassium permanganate to react in concentrated solution with iodine after the addition of a small quantity of potassium hydroxide. The iodine was probably dissolved by the hydroxide with the formation of iodide and iodate, and the iodide was then converted to iodate by the permanganate. At any rate, the products of the reaction were, as in the previous instance, potassium iodate, potassium hydroxide, and manganese dioxide, the hydroxide being formed in smaller proportions than before. The potassium iodate was obtained from the solution by crystallization as described above. Both portions of iodate were combined and purified by one recrystallization from aqueous solution, with centrifugal drainage.

---

[1] Baxter and Tilley, *Loc. cit.*

From the potassium iodate barium iodate was next prepared by adding to a hot solution of the potassium iodate a hot solution of a nearly equivalent amount of barium hydroxide. The precipitated barium iodate was very carefully washed by decantation with cold water. Very little loss of material takes place during this washing since the barium iodate is only slightly soluble in cold water. The barium iodate, suspended in a comparatively small amount of water, was then converted into barium sulphate and iodic acid by means of an approximately equivalent amount of sulphuric acid at boiling temperature. Since reactions of this sort, which involve the change of one solid into another, progress to completion only with difficulty, the barium sulphate was left in contact with the solution for several days with intermittent heating and shaking. Finally the solution of iodic acid was separated from the barium sulphate by decantation, and was evaporated to small bulk in a platinum dish. Further decantation allowed the removal of traces of barium sulphate which were suspended in the original decantate. The solution was finally evaporated to crystallization in the platinum dish. Somewhat more than a kilogram of iodic acid was prepared in this way.

The final purification of the acid was effected by a long series of crystallizations, as described in the latter part of the paper by Baxter and Tilley.[1] The first mother liquor was found to contain a slight excess of sulphuric acid. This was shown to have been eliminated during the first crystallizations by reducing portions of the mother liquors and testing for sulphate. The barium sulphate, whether dissolved or suspended, was effectually removed during the crystallizations, the solution of acid being occasionally decanted from traces of insoluble material which were present during the first crystallizations. In all, this iodic acid was subjected to eleven crystallizations, the usual process of fractional crystallization being followed in order to avoid too serious loss of material owing to the high solubility of iodic acid, even at ordinary temperatures.

Since chlorides and bromides are not converted to the salts of the oxyhalogen acids by permanganate, it seems probable that the first portion of potassium iodate was free from the corresponding salts of chlorine and bromine. Whether this is true of the second portion, made from iodine, is doubtful, since if the original iodine contained these two elements they would have dissolved in the alkaline solution with the production, to some extent, of chlorate and bromate. Later, however, after the conversion of the iodate to iodic acid, free chloric and possibly bromic acids must have been either vaporized or decomposed during the subsequent treatment.

---

[1] THIS JOURNAL, 31, 216 (1909).

This material differed in its preparation from that used in the earlier determinations of the ratio of silver to iodine pentoxide, and hence a portion of it will soon be used for new determinations of the latter ratio. Iodine made from this iodic acid is designated Sample II.

For comparison with the iodine obtained from the iodine pentoxide, two experiments were made with a third specimen similar to the iodine used in the earlier determinations of the ratio of silver to iodine. This iodine was first distilled from solution in potassium iodide. The product was thus freed from all but traces of chlorine and bromine. Next it was converted into hydriodic acid by suspending the iodine in water and passing hydrogen sulphide through the solution until reduction was complete. The solution of hydriodic acid was boiled to coagulate the sulphur and was filtered. In order to free the hydriodic acid from hydrocyanic acid which might have had its source in iodide of cyanogen contained in the original material, the solution was boiled for several hours until the concentration approached that of the constant-boiling solution. From this hydriodic acid the iodine was set free by the addition of a very nearly equivalent amount of potassium permanganate and distillation into a flask cooled with running water. In this way, since only five-eighths of the iodine is set free by the permanganate, the iodine was a second time distilled from an iodide. The product was distilled once with steam, and after drainage was dried over concentrated sulphuric acid. This specimen is designated Sample III.

Silver.—Several samples of silver were used, most of which have been employed in other similar investigations. Sample A was purified by Mr. A. C. Boylston for work upon the analysis of phosphorus tribromide.[1] This material was prepared by first precipitating the silver as chloride from strongly acid solution, with subsequent reduction by means of sodium hydroxide and sugar. The metal was fused upon charcoal before a blowpipe and the surface impurities were removed from the buttons by scrubbing with sea sand and etching with dilute nitric acid. The cleansed buttons were dissolved in nitric acid, and the solution, after neutralization, was precipitated with ammonium formate which had been prepared with distilled materials. The metal was thoroughly washed with water and was again fused with even more care than before in a crucible lined with the purest lime. The resulting buttons were in turn cleansed by etching with dilute nitric acid and were next converted into electrolytic crystals in a cell in which a concentrated, nearly neutral solution of silver nitrate served as electrolyte, and a pile of the buttons served as anode, the cathode being a stick of very pure silver from another preparation. After the crystals had been very thoroughly washed with water, they were fused in a current of hydrogen in a porcelain boat lined with the purest lime. The boat was provided with cavities so that the buttons of silver varied considerably in size, from 2 to 5 grams. The final product was cleansed from adhering lime by etching with dilute nitric acid and, after being washed with the purest water, it was dried, first in air at 100°, finally in a vacuum at about 500°.

---

[1] Not yet published.

Sample B was prepared in an exactly similar fashion by Dr. H. C. Chapin for work upon the atomic weight of neodymium,[1] except that it was necessary to cut the product into smaller fragments by means of a jeweler's saw. Surface contamination with iron from the saw was removed by etching with successive portions of dilute nitric acid until the acid remained free from iron. Sample C was purified by Mr. Victor Cobb for work upon the analysis of ferrous bromide in a way exactly similar to that used in the purification of Sample A.[2] Sample D was used in an investigation upon the atomic weight of bromine.[3] This material had been precipitated once as silver chloride. The product was reduced with sodium hydroxide and sugar and was twice deposited electrolytically as described above in the case of Sample A.

These methods of purification have already been discussed and shown to be efficient in several papers from this laboratory, especially by Richards and Wells.[4] As will be seen later, the different specimens of silver all gave essentially identical results in this investigation. Several of them have already been compared, with a like outcome.

The Ratio of Silver to Iodine.

In the earlier determination of the ratio of silver to iodine the method employed was as follows: Iodine was sublimed into a weighed tube; next, after being weighed, it was reduced by means of sulphurous acid, and the very dilute solution of iodide was precipitated with a very dilute solution of an equivalent amount of silver nitrate. The end point was then determined in a nephelometer.

In the present instance certain very considerable modifications of the earlier method were made. In the first place, owing to occlusion of silver sulphate by silver iodide, sulphurous acid has been found to be unsuitable as a reducing agent,[5] hence hydrazine hydroxide was substituted. The products of reduction were, therefore, only nitrogen gas and hydriodic acid. In the second place, in the investigation upon the ratio of silver to iodine pentoxide it was found that, even if exactly equivalent amounts of silver and iodine are employed, the end point as determined in a nephelometer is somewhat uncertain, owing to the great dilution of the mother liquor and, in all probability, to disturbances due to traces of colloidal precipitate.[1] Therefore, as in the investigation upon iodine pentoxide, instead of attempting to determin the end point in this way, a very slight excess of silver was used, and the excess was found by evaporating the mother liquor to very small bulk and then estimating the silver gravimetrically as silver iodide. Owing to the strong tendency of silver iodide permanently to occlude silver nitrate, the excess of silver was very small indeed, as a rule less than 0.2 milligram. Furthermore, both the solution of the iodide and the solution of silver nitrate were made very dilute before precipitation in order to avoid as far as possible the aforesaid occlusion. In the third place, much larger quantities of material were employed so that accidental errors should be of less significance.

In all but the last three experiments the tube in which the iodine was weighed was of glass, about 18 centimeters long and 1.8 centimeters in external diameter. The ends of the tube were constricted and were provided with well fitting ground-glass caps in order to avoid vaporization of the iodine during the weighing of the tube and the subsequent manipulation.

The iodine was prepared for weighing by first dehydrating a suitable quantity of iodic acid in a platinum boat in a current of pure dry air, as described in the paper upon the analysis of iodine pentoxide. The air was purified by being passed over hot copper gauze, and then through a system of towers containing in succession glass beads moistened with silver nitrate solution, a solution of potassium hydroxide containing potassium permanganate, and concentrated sulphuric acid containing a small amount of potassium dichromate. The final drying of the air was effected with phosphorus pentoxide which had been freshly sublimed in a current of oxygen. The apparatus was constructed wholly of glass with fused joints. The boat containing the iodic acid was placed in a hard glass tube through which the current of air was passed, the tube being heated by means of the solid aluminium oven which has been described elsewhere.[2] The first stage of the dehydration of iodic acid takes place rapidly at 100° if it has been previously ground with a small percentage of the substance produced in the first stage of the dehydration, $HIO_3.I_2O_5$. Inoculation with this phase not only reduces the temperature at which the dehydration begins, but also diminishes the proportion of moisture finally retained by the pentoxide.[3] As soon as water ceased to be given off, the temperature was raised until the second and final stage in the dehydration began, at about 220°. Finally the pentoxide was

[3] Baxter and Tilley, THIS JOURNAL, 31, 212 (1909).

heated for one hour at 240°. Iodine pentoxide which has been dried in this way has been found to contain only a little over 0.002 per cent. of residual moisture.[1] The water formed during the dehydration was, of course, carefully expelled by heating the hard glass tube.

Next the iodine pentoxide was converted into iodine and oxygen by heating the section of the tube containing the boat to about 350°. The iodine was allowed to condense in the cooler portions of the tube beyond the boat, although, of course, a slight loss of iodine took place. During this decomposition it seems certain that the trace of residual moisture in the pentoxide must have been eliminated. Nevertheless, for the sake of certainty, before the iodine was sublimed into the weighing tube, it was heated slightly above its melting point, 114°, in the current of dry air. The weighing tube was then placed in position, with the constricted end of the hard glass tube inserted for a short distance into one end of the weighing tube, the weighing tube being supported upon a glass stand. The iodine was slowly sublimed into the weighing tube by gently warming the hard glass tube. Finally the iodine in the weighing tube was heated to fusion and allowed to solidify. The caps were placed on the weighing tube, which was allowed to stand near the balance case, under a bell jar containing concentrated sulphuric acid, for several hours. During the manipulation the weighing tube was handled only with clean, cork-tipped forceps.

Since during the sublimation of the iodine the hard glass tube must have been slightly attacked, and since it is possible that alkali iodides thus formed could have been carried into the weighing tube with the iodine, a quartz tube was substituted for the hard glass tube after the first five experiments. This tube was provided with several constrictions beyond the section in which the boat was placed, which served the purpose first of preventing to a considerable extent the conduction of heat along the tube, and second, of preventing back diffusion of iodine. Since a small amount of undecomposed pentoxide was carried along by the rather rapid current of oxygen evolved during the decomposition, the first constriction in the quartz tube was loosely filled with a roll of platinum gauze which was heated to redness, so that any pentoxide which reached this constriction must have been completely converted to iodine and oxygen. As a matter of fact, neither of these changes produced any perceptible effect upon the results.

When iodine from Sample III was employed, it was sublimed from a platinum boat into the quartz tube and once again from one portion of the tube to another before the final sublimation into the weighing tube.

In order to reduce the iodine to hydriodic acid, it was next dissolved in a solution of an excess of hydrazine hydroxide. A thick-walled flask of Jena glass holding nearly two liters was provided with a column of bulbs carefully ground into the neck. In the flask was placed a quantity of a solution of hydrazine hydroxide considerably more than sufficient to combine with the iodine. The hydrazine was made from the sulphate by distillation in a platinum still with an excess of sodium hydroxide, and was redistilled before use. The weighing tube containing the iodine was carefully introduced into the flask, the stoppers being removed in the process, and the column of bulbs was put in place immediately after the introduction of the iodine tube. In this manipulation a small quantity of iodine vapor may have escaped from the tube during the very short time in which it was exposed to the air. However, since the total amount of iodine vapor contained by the tube at 20° was not greater than 0 03 milligram,[1] and since certainly only a small fraction of the total vapor could have escaped into the air outside the flask, and especially since the interior of the flask and the column of bulbs had been moistened with hydrazine solution shortly before the iodine tube was introduced so that any iodine vapor in the flask must have been quickly absorbed, the error from this source must have been very small. The solution of the iodine in hydrazine progresses too rapidly if the iodine has not been previously fused, for crystals of iodine, on account of their large surface, reduce so rapidly that the current of nitrogen issuing from the flask might possibly carry with it traces of iodine vapor. Since acid is produced in this reaction, it was found advantageous to keep the solution nearly neutral by the occasional addition of redistilled ammonia. This had two advantages: first it accelerates the rather slow solution of the fused iodine; secondly, it prevents the possible escape of hydriodic acid vapor from the flask. Several tests in which the nitrogen evolved in the reduction was caused to pass from the top of the column of bulbs through a trap sealed with water showed that in fact no iodine was lost in this way.

---

[1] Baxter and Tilley, THIS JOURNAL, 31, 212 (1909).

After the dilution of the iodide solution to a volume of about one and one-half liters, it was transferred for precipitation to an 8-liter bottle with a carefully ground stopper. Whether or not the solution was ammoniacal at this point, about 25 cc. of constant boiling nitric acid were introduced, after the acid had been diluted to a volume of one liter and boiled to destroy nitrous acid; for unless the nitric acid is free from nitrous acid, iodine is set free. The bottle was immediately stoppered after the addition of the nitric acid, and was allowed to stand for some time after any liberated iodine had been reduced by the excess of hydrazine. In all but the earlier experiments the acid was introduced through a long thistle tube at the bottom of the bottle, so that iodine could not reach the surface of the solution until after the bottle was closed. The amount of iodine set free in this way was, however, in no case large enough to have caused appreciable loss by evaporation. If the solution did not at this point have a total volume of nearly four liters, it was next diluted to this volume.

---

[1] The vapor pressure of iodine at 20° is 0.2 mm. Baxter, Hickey and Holmes, THIS JOURNAL, 29, 127 (1907). The interior volume of the tube was less than ten cubic centimeters.

A quantity of silver, a very few tenths of a milligram, in excess of the amount necessary to combine with the iodine, was weighed out, the greater part being in buttons weighing several grams each, the final adjustment of the weight being made with tiny ignited electrolytic crystals. This silver was dissolved in redistilled nitric acid which had been diluted with an equal volume of water, in a flask provided with a column of bulbs to catch possible spatterings. The silver was dissolved so slowly, however, that very little effervescence took place, nitrous acid rather than nitric oxide being formed. The solution was then further diluted and heated until free from nitrous acid. Next the silver nitrate solution was diluted to a total volume of nearly four liters and then was slowly added to the solution of hydriodic acid in the precipitating bottle, with continual agitation during the precipitation. The precipitating bottle was shaken violently for a short time, and was allowed to stand for at least one week with occasional shaking until the supernatant liquid seemed to be absolutely clear. The clear liquid was then filtered through a Gooch-Munroe-Neubauer crucible with a very dense mat of platinum sponge, so that, although the filtration proceeded slowly, there seemed to be certainty that every particle of suspended silver iodide was removed during the filtration. The filtered solution was evaporated to a very small bulk, until the greater part of the free nitric acid had been expelled. Toward the end of the evaporation small quantities of silicic acid separated out. Consequently, before the precipitation of the silver in the evaporated filtrate, it was filtered a second time through the Neubauer crucible. The total volume of the solution, after the second filtration, was not more than 100 cc. and frequently was as small as 50 cc. To this solution was added a quantity of a solution of pure hydriodic acid large enough completely to precipitate the silver. Several days' standing were usually necessary to insure sufficient coagulation of the opalescent silver iodide for filtration. Then the precipitate was collected upon a small weighed Neubauer crucible, and, after being heated to about 200°, it was weighed. In order to show that no silver iodide was lost in this filtration, in several instances the filtrate was evaporated to small bulk and tested nephelometrically for silver, always with essentially negative results. The quantity of silver used in each experiment was so carefully adjusted before precipitation that the silver content of the filtrate seldom amounted to more than 0.5 milligram, and in all but two of the later experiments it was less than 0.2 milligram.

During every experiment the glass tube in which the iodine was weighed lost slightly in weight. In a few cases the loss amounted to as much as 0.3 milligram, although in many it was hardly more than 0.1 milligram. This loss in weight was probably due in part to the action of the iodine on the glass with the formation of soluble iodides. Since these iodides would have dissolved during the reduction of the iodine, the error from this source must have been considerably less than the loss in weight of the tube. Furthermore, it is very probable that the loss in weight of the weighing tube was caused in part by the solvent action of the ammoniacal hydrazine solution and possibly to mechanical abrasion of the ground surfaces during the manipulation.

In the last three experiments the glass weighing tube was replaced by a similar quartz tube with glass caps. Although the loss in weight was somewhat diminished by this change, it was not wholly prevented, the losses in the first two of the three experiments being 0.00010 and 0.00020 gram, respectively. In these three experiments it is more probable that the difficulty was due to the solvent action of the hydrazine solution and to abrasion than to action of the iodine on the quartz. If this is the case, the results would not be at all affected by the loss in weight of the tube.

One of the chief dangers in these experiments lies in the occlusion of silver nitrate by the silver iodide. For this reason the solutions were made as dilute as possible before precipitation. In the first ten analyses the volumes of the two solutions before precipitation were nearly four liters, while in the last three analyses the volumes were between seven and eight liters. Hence the concentrations varied between eightieth normal in analysis 5 and thirtieth normal in analysis 2. The fact that the results seem to be independent of the concentrations is strong evidence that the occlusion could not have been very serious. The attempt was made, however, to secure further evidence that this occlusion was negligible by conducting the precipitation in two analyses (9 and 10) in reverse fashion, *i. e.*, by pouring the hydriodic acid solution into the silver nitrate solution. Although the opportunity for occlusion of silver nitrate was evidently very much greater in these two experiments than in the others, the results of analyses 9 and 10 agree so well with those of the others that very little doubt can exist that the occlusion of silver nitrate had been prevented. Similar evidence was obtained in the analysis of iodine pentoxide.[1]

The solubility of silver iodide has been found by Kohlrausch[2] to be only

[1] THIS JOURNAL, 31, 218.

[2] *Z. physik. Chem.*, 50, 355 (1904).

0.0000035 gram per liter at 21°. In 8 liters of mother liquor there would be dissolved then only 0.00003 gram of silver iodide while the wash waters would contain a trace more. The correction for the equivalent amount of silver or iodine would not amount to more than 0.0002 per cent. in any one of the first ten analyses. In the last three analyses the volume of the mother liquor was at least 16 liters. Hence the dissolved silver iodide amounted to 0 00006 gram. However, since larger quantities of material were used in the last three experiments, the percentage correction due to solubility is no greater.

Evidence that the Neubauer crucible was an effective filtering medium is to be found in the fact that in many of the analyses the quantity of silver iodide obtained from the filtrate was not much greater than the amount which should have been dissolved. Furthermore, in one analysis, the only one completed which is not recorded in the following table, the filtrate was found to contain only a mere trace of silver. The crucible which was employed in all the analyses, with a water pump vacuum, allowed from one to two liters of solution to pass per hour.

In the following table are given the results of all the analyses which were completed, with the exception of the one mentioned above in which no silver was found in the filtrate The silver used in this experiment, if it was exactly equivalent to the iodine, yielded a ratio of silver to iodine very close to the other analyses, 0 849016, but on account of the uncertainty as to whether the silver was sufficient to combine with the iodine, and because the analysis met with a slight accident, it has been considered wiser to omit this result in computing the average.

The weights of the silver and the iodine are corrected to the vacuum standard by subtracting 0.000031 gram for each apparent gram of silver and adding 0 000099 for each apparent gram of iodine.[1] The weights were carefully standardized by the method described by Richards.[2]

Results and Discussion.

A careful examination of the following table shows that neither the variations in the specimens of silver and iodine employed, nor those in the methods of analysis produced appreciable effects upon the results. The extreme difference in the ratio of silver to iodine is 0 007 per cent.; but all except three of the results agree within 0.003 per cent. and the last ten analyses within 0.005 per cent. The final average is 0.005 per cent. lower than the result previously obtained, 0.849943, while no one of the thirteen analyses yielded a result as high as the above figure. This outcome confirms the suspicion previously expressed on page 1591 that the silver iodide obtained in the earlier determinations of the silver-iodine ratio was contaminated by occluded impurities.

						Average,	0 849906

When the average ratio is combined with that of silver to iodine pentoxide, 0.646230, the atomic weights of silver and iodine are found to be 107 864 and 126 913, respectively. On the basis of 107 864 for the atomic weight of silver, the older value of the silver-iodine ratio yields 126.907 as the atomic weight of iodine, *i. e.*, the newer value raises the apparent atomic weight of iodine referred to silver by 0.006 unit. It is of interest to note that a positive error of 0.0003 per cent. in the ratio of silver to iodine is necessary to lower the apparent atomic weight of silver by one one-thousandth of a unit, while a negative error of 0.0002 per cent. in the ratio of silver to iodine pentoxide produces the same effect. The agreement of the final value for the atomic weight of silver with that recently found by Richards and Willard, 107.871, is as satisfactory as could be expected from consideration of the widely different methods employed in the two researches. There seems to be little doubt that the atomic weight of silver lies nearer 107.87 than 107.88, the commonly accepted value. Further evidence upon the ratio of silver to iodine is desirable, and it is intended to pursue the investigation by new determinations of the ratio of silver to silver iodide and of silver chloride to silver iodide.

I am very greatly indebted to both the Carnegie Institution of Washington and the Cyrus M. Warren Fund for Research in Harvard University for indispensable platinum and quartz apparatus.

THE ATOMIC WEIGHT OF VANADIUM.

BY D. J. MCADAM, JR.

Received October 21, 1910.

Introductory.—In this laboratory, use has frequently been made of dry hydrochloric acid gas in making various separations, and in several atomic weight determinations.

Smith and Hibbs[2] found that vanadium, as well as a number of other substances, could be completely volatilized from their alkali salts by heating in a current of dry hydrochloric acid gas. It therefore seemed probable that this method might be used in determining the atomic weight of vanadium. A new determination of the atomic weight of this element would be particularly desirable since the results obtained by previous investigators differ widely.

Historical.—Berzelius, in 1831,[3] made four determinations of the atomic weight of vanadium. In three of these he reduced V_2O_5 to V_2O_3 by heating in a stream of hydrogen; in the fourth, he reoxidized the V_2O_3 to V_2O_5. As the average of four fairly concordant results, he obtained a value which corresponds to 52 46, referred to oxygen as 16. As Roscoe pointed out later, Berzelius' material undoubtedly contained phosphorus, a small trace of which interferes greatly with the reduction of V_2O_5 to V_2O_3. The ammonium molybdate test for phosphoric acid was unknown in Berzelius' time.

Roscoe, in 1867,[4] made four determinations by the method of Berzelius, using material carefully purified in several different ways. The average of the four results was 51 371, but the maximum and minimum differed by nearly one-half of one per cent.

He also obtained a series of nine values by determining the amount of silver required to precipitate the chlorine from vanadium oxychloride, $VOCl_3$. He did not use the proper end point for this reaction, but the final results would not be affected very much by this error. Loss of chlorine on treatment of the $VOCl_3$ with water was probably a more serious source of error.

In still another series of eight experiments, Roscoe weighed the silver chloride obtained from a known weight of vanadium oxychloride. He does not mention any correction for the solubility of the silver chloride in the wash water; if this was neglected, his value for the percentage of chlorine is too low, and consequently his value for the atomic weight is too high. The variation in the percentage of chlorine in these seventeen experiments is from 60.86 to 61 55, or about 1.13 per cent. This, of course, means a variation in the calculated molecular weight of $VOCl_3$ of 1.13 per cent.; and, since the atomic weights of oxygen and chlorine are assumed to be known, all this variation would apply to the vanadium alone, and would amount to about 3.4 times 1.13, or 3.84 per cent. For example, the maximum calculated value for the atomic weight would be 52.39, and the minimum 50.44. The average of his results by both methods is 51 24.

---

For over forty years our knowledge of the atomic weight of this element rested entirely on the work of Roscoe. Within the last year, however, two articles on the atomic weight of vanadium by Wilhelm Prandtl and Benno Bleyer have appeared.[1] These authors have used the same methods that were used by Roscoe, but have used great care in avoiding the sources of error in the work of the earlier author.

The vanadium oxychloride was carefully purified and kept out of contact with air until it had been weighed. Moreover, on treatment of the oxychloride with water, they reduced the vanadium to the valence of four by means of pure zinc, and thus avoided loss of chlorine.

In order to make allowance for the solubility of silver chloride in water, they prepared twelve wash waters by washing the silver chloride precipitated in the first experiment in each series; the twelve filtrates, in the same order, were used to wash the silver chloride in the remaining experiments of the series.

In the first article published by Prandtl and Bleyer are given the results of two series of experiments by this method. In Series I, consisting of five determinations (the first one being of course rejected), the average percentage of chlorine obtained from the oxychloride was 61.3095 ± 0.0158; the maximum was 61.352 and the minimum 61.284, a variation of 0.11 per cent. This variation, when applied to the vanadium content would be multiplied by 3 4, making 0.37 per cent. variation in the calculated value for the atomic weight. The average value for the atomic weight in this series is given as 51.133 ± 0.013. The authors, however, have overlooked the fact that the probable error in the percentage of chlorine must be multiplied by 3.4 to give the probable error in the atomic weight of vanadium; so it should be ±0.044 instead of ±0.013.

In Series II, consisting of six determinations, the average percentage of chlorine was 61.3696 ± 0.0098, the extremes being 61.405 and 61.348, a variation of 0.093 per cent. This would correspond to a variation of 0.316 per cent. in the atomic weight. The average value for the atomic weight in this series is 50.963, and the probable error as before should be multiplied by 3.4, giving ±0.027 instead of 0.008. As a mean of the two series, they get 51.048 ± 0.010, but it should be 51.048 ± 0.034.

In the second article by the same authors, they have a third series of four accepted values, varying from 61.301 to 61.333 for percentage of chlorine. As an average for the thirteen accepted values of all three series, they obtain 51.061.

---

[1] *Z. anorg. Chem.*, 65, 152; and 67, 257.

In the same article are recorded the results of four determinations by the method of Berzelius. In this series they obtained results that are considerably higher, giving an average of 51.374 ± 0.033; but they found that the V_2O_3 takes up oxygen so rapidly that the weight of the compound cannot be obtained with any certainty. It is therefore probable that the observed weights of V_2O_3 are too great, and consequently the calculated values for the atomic weight are too high.

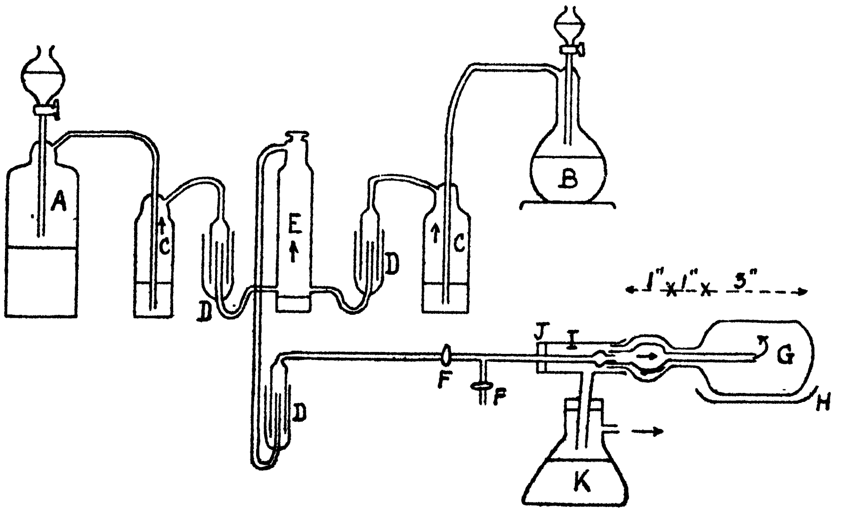
The discrepancies in the results of this careful investigation have thus made more evident the need for a redetermination for the atomic weight of vanadium by a new method.

Method and Apparatus.

The salt of vanadium used in these experiments was sodium metavanadate ($NaVO_3$), the most stable of the vanadates of sodium. Some attempts were made to use other vanadates of sodium, but they were found to be unstable or indefinit.

The metavanadate was heated in hydrochloric acid gas in order to drive out the vanadium and leave sodium chloride. Since the hydrochloric acid has a tendency to reduce vanadates, it seemed probable that a mixture of hydrochloric acid gas and chlorine would drive out the vanadium more readily than the hydrochloric acid alone. Experiments proved that the presence of a small proportion of chlorine had a good effect.

The gas generators and drying apparatus were constructed entirely



of glass, with connections of ground glass or sealed by sulphuric acid; the vessel in which the sodium vanadate was heated was of quartz.

The arrangement of the apparatus is shown in the figure.

In the vessel A, the hydrochloric acid gas is generated by allowing concentrated sulphuric acid to drop into strong hydrochloric acid solution. In B, the chlorine is generated by allowing hydrochloric acid to drop into the flask containing pure potassium permanganate moistened with water. C, C, are drying vessels containing sulphuric acid. D, D, D, are connectors in which sulphuric acid is placed so as to make the connection air-tight. E is a drying tower, containing glass beads moistened with sulphuric acid. F, F are stopcocks so arranged that the gas from the generators can be shut off and a current of pure air substituted. G is the flask containing the sodium vanadate; it is supported by the quartz dish H. I is a tube of hard glass. J is a rubber stopper through which the tube from the gas generator passes. K is a flask containing water, through which the acid fumes from the generator are drawn by suction.

Preparation of Pure Material.

Water.—The distilled water of the laboratory was redistilled once from alkaline permanganate, rejecting the first fourth of the distillate. It was then redistilled twice more, the last time with a block tin condenser; in some of the later preparations a quartz condenser was used. The water seal invented by T. W. Richards was used in all distillations.

When used for crystallizations, the water was either allowed to run from the condenser directly into the platinum dish, or was collected in a quartz flask.

Sodium Metavanadate.—The chief source was iron vanadate that is used in the preparation of ferro-vanadium. It contained not more than a trace of phosphorus or molybdenum.

The iron vanadate was changed to sodium vanadate by boiling with caustic soda or sodium carbonate, filtering off the ferric hydroxide, and evaporating the filtrate to crystallization. It was purified by several different methods, and its freedom from phosphorus and molybdenum was tested and proved.

Sample A.—A mixture of vanadic acid and acid vanadate of sodium was boiled with a slight excess of C. P. sodium carbonate. It was then recrystallized five times in glass from ordinary distilled water, and twice in platinum from twice distilled water. The crystallization was carried on in a room free from acid fumes, so in this sample no special precautions were taken to keep the material out of contact with the air of the room. The sample was dried and preserved in porcelain dishes in a desiccator, over sulphuric acid, that had been boiled with ammonium sulphate.

Sample B.—Some metavanadate containing phosphate, was recrystallized a few times, rejecting the first crop of crystals each time. The phosphate was thus almost completely removed. The partially purified metavanadate was now recrystallized six times in glass and once in platinum from twice distilled water, being drained by suction each time.

It was next crystallized six times more in platinum by dissolving in hot water, cooling, and distilling into the dish some twice distilled alcohol. The substance separated out in small crystals and settled rapidly, leaving a large volume of liquid, which was poured off. It was next recrystallized twice from water, by allowing the crystals to form slowly without stirring. For each crystallization several weeks were required, and considerable liquid was left, which was poured off. The substance was dried and kept in a desiccator over caustic soda.

Sample C.--Some sodium vanadate, which had been crystallized several times, was recrystallized twice more in porcelain, from ordinary distilled water. It was then recrystallized in platinum, three times from ordinary distilled water and three times from thrice distilled water. It was kept in a desiccator over caustic soda during crystallization.

Centrifugal drainage was used during the last five crystallizations, the material being rotated in a perforated platinum cone. Not enough time was allowed to each crystallization, consequently the crystals formed in a pasty mass, which did not drain well. This error was avoided in later preparations.

The crystals were now dissolved in hot water and allowed to stand in a desiccator over caustic soda; crystals formed slowly and the remaining liquid was poured off. The solution was yellow at first, but as crystallization proceeded it became colorless.

Sample D.—The mother liquor from sample C was put in a desiccator over caustic soda and allowed to evaporate to dryness. A little over two grams were obtained, and this was used later as a test for the neutrality of sample C.

Sample E.—Since later results indicated that sample C still contained excess of alkali, a portion of it was recrystallized twice more, with centrifugal drainage, and was washed each time with a little distilled water. The crystallization was allowed to take place slowly; so the substance was not pasty as in sample C, and drained readily, giving a light yellow filtrate. Contact with the air of the room was prevented as much as possible by keeping it in a desiccator over caustic soda during crystallization.

The material had now been put through eleven crystallizations altogether, and later results indicated that it was free from excess of alkali.

Sample F.—Crude sodium vanadate was acidified with sulphuric acid and the precipitated vanadic acid washed repeatedly with distilled water; it still gave a test for sulphuric acid.

It was then treated with a large quantity of water and reduced to vanadyl oxalate by heating with oxalic acid. A slight excess of ammonium oxalate was added and the double ammonium oxalate crystallized out on evaporation and cooling. After three crystallizations, with drainage by suction, no trace of sulphate could be detected, and the material was probably free from phosphoric and molybdic acids.

By addition of excess of ammonia, a brown precipitate of ammonium vanadite was obtained, which was filtered and washed several times. It was then heated to get rid of ammonia, and fused with sodium carbonate. The water solution was still greenish, so the oxidation was completed by addition of a little sodium peroxide. The analyses of the sodium carbonate and sodium peroxide, according to J. T. Baker, showed th following:

	Na_2CO_3 Per cent.		Na_2O_2. Per cent.
Fe	0.0005	Fe	0.003
Al_2O_3	0.0002	Al_2O_3	0.001
CaO	0.008	Cl	0.007
SiO_2	0.001	SO_3	0.001
A	0.085	Na_2O_2	83.1
SO_3	0.001	CO_2	0.32
H_2O	0.95		

The sodium vanadate was now crystallized eight times in porcelain and three times in platinum from ordinary distilled water, suction being used after each crystallization. It was now practically neutral to phenolphthalein. It was next crystallized four times more from thrice distilled water, each time with centrifugal drainage and washing. The last three times the distilled water came in contact with nothing but quartz and platinum.

Special precautions were taken to avoid contact with carbon dioxide of the air during the last few crystallizations.

The effect of carbon dioxide of the air could be only slight, but experiments showed that it affects the equilibrium to a certain extent. To show the effect of carbon dioxide, the gas was prepared by the action of dilute sulphuric acid on sodium bicarbonate, and passed through two bottles of sodium bicarbonate solution, and thence through a vessel containing glass beads moistened with water. The purified gas was then passed into some of the nearly colorless solution of metavanadate, and soon turned the solution deep orange-red. The equation might be epresented as follows:

$$4NaVO_3 + H_2O + 2CO_2 = Na_2V_4O_{11} + 2NaHCO_3.$$

On boiling this orange-colored solution, or putting it in a desiccator over caustic soda, the reverse reaction takes place, carbon dioxide is given off, and the solution becomes colorless. If the metavanadate contains excess of alkali or sodium carbonate, only a faint yellow color appears on passing in carbon dioxide, since the increased mass of bicarbonate favors the reverse reaction.

Metavanadate solutions are usually colorless when hot, and yellow when cold, but an experiment tried on some of the pure material seems to indicate that the yellow color is due to traces of acid vanadate caused by carbon dioxide of the air. A solution of the metavanadate, which was light yellow in color, was heated to boiling in a glass flask. On cooling in contact with the air, a yellow color appeared; but if the flask was stoppered while the liquid was boiling, no color appeared on cooling.

These experiments prove that carbon dioxide of the air can have no effect on the solutions when they are hot; and therefore its effect would be negligible in preparing sodium metavanadate, if the material is kept in a desiccator over caustic soda. The substance which had thus been put through fifteen crystallizations was cream colored. It was neutral in hot or cold solution to methyl orange, litmus or phenolphthalein. The fused substance was colorless and transparent.

Hydrochloric and Sulphuric Acids.—For all but the last two experiments, ordinary C. P. acids were used. Since the method of generating the hydrochloric acid gas was a purification in itself, it was thought that the ordinary acids would be sufficiently pure.

If the hydrochlroic acid contained any hydrobromic acid, the bromine would be set free and driven out by the action of the chlorine. No arsenic would remain with the sodium chloride in the final weighing, since it is easily volatilized by heating in contact with hydrochloric acid gas. Any sulphur dioxide in the sulphuric acid would be oxidized by chlorine and remain in the drying vessels.

Nevertheless, in the last two experiments, special hydrochloric and sulphuric acids were used, containing no arsenic, nitric acid, or sulphurous acid, and only a trace of iron, according to the analysis of J. T. Baker.

Balance and Weights.—A Staudinger balance, sensitive to 0.00001 gram, was used in these experiments. It was kept in the basement, in a room that was used for no other work; the balance rested on a brick and stone support that was sunk directly into the ground.

The weights were kindly loaned by Professor Franklin of the Physics Department of Lehigh University. The larger weights were of brass, gold-plated, and the smaller weights were of platinum. They were carefully standardized, and allowance was made for the buoyancy of the air; the standardization was repeated several times in the course of the experiments.

All weighings were by substitution, and were corrected for the buoyancy of the air. A counterpoise was always used of the same size and material as the vessel to be weighed, and the vessel was always left near the balance for several hours before weighing.

Dehydration of the Sodium Metavanadate.—The powdered substance, when heated for several hours at 385°, still retains about 0 05 per cent. of moisture. It melts at a dull red heat, and on cooling forms white radiating crystals, slightly hygroscopic. If heated for a time at bright redness, it appears to lose weight continuously, although very slowly; by fusion at dull redness, however, it is easy to get a constant weight.

Specific Gravity of Anhydrous Sodium Vanadate.—The specific gravity of the fused salt was determind by putting a known weight of the substance into a pycnometer, filling the pycnometer with alcohol and weighing it.

The weight of alcohol required to fill the pycnometer was 14.593; the weight of sodium vanadate used was 5.4375, and the weight of the sodium vanadate and alcohol required to fill the vessel was 18.4335. Therefore the weight of alcohol displaced by the vanadate was 14 593 — (18.4335—5.4375) = 1 600. Since the specific gravity of the alcohol was 0.82, the specific gravity of the sodium vanadate is 5.437/1.600 × 0.82 = 2.79.

Corrections for Buoyancy of the Air.

The correction for the weight of one gram of sodium vanadate is equal to the weight of 1 cc. of air multiplied by the difference between the volume of 1 gram of vanadate and 1 gram of weights. The temperature varied from 20 to 30° in the progress of the experiments, but the pressure did not vary much from 750 mm., so the correction was calculated for 25° and 750 mm. The weight of 1 cc. of air under these conditions is 0.00117, the volume of 1 gram of vanadate is 0.358 and of 1 gram of brass 0.119; therefore the correction for 1 gram of vanadate is 0.00117 × (0.358–0.119) = +0.00028. For 1 gram of sodium chloride, using the accepted value 2 14 for the specific gravity, the correction is 0.00117 (0.468–0.119) = +0.00041.

Experiments and Results.

Several modifications of the vessel used to contain the sodium vanadate were tried before a satisfactory form was found.

It was found impossible to remove all vanadium from the vessel unless a fresh surface of material was frequently exposed to the action of the gases. This could be done only by moistening the substance and again drying it. To admit of this treatment, a flask, G, of the form shown in the figure, was designed; the flask and inner tube were made of quartz. The small bulbs prevent loss of sodium chloride by decrepitation.

In order to get the weight of the sodium vanadate, it was fused in a platinum capsule and rotated just before solidifying, so as to spread the substance in a thin layer; the total weight of capsule, vanadate and a platinum rod was then taken. By means of the platinum rod, the vanadate was then broken up and as much as possible transferred to the weighed quartz flask, which was held vertically. After again heating the capsule and rod, the loss in weight indicated the amount of sodium vanadate transferred to the flask.

The apparatus was now adjusted and hydrochloric acid and chlorine were passed through the quartz vessel while it was heated. The quartz dish H was heated by a Bunsen burner, and two other burners were arranged above the vessel, so as to radiate sufficient heat downward; a small flame was also placed under the exit tube and thus any crawling of material was prevented.

When as much as possible of the vanadium had been removed, a little water was added to the substance in the flask, and it was again dried in the stream of gas, being rotated at the last in order to spread the material over the inner surface of the vessel.

In this process, the sodium chloride first dissolved in the water, leaving the vanadium; then, as the hydrochloric acid was passed in, the vanadium dissolved and the sodium chloride crystallized out. As the liquid evaporated, the vanadium compound was left on the surface, where it could be attacked by the gases.

After three or four of these treatments, the vanadium could all be driven out of over nine grams of vanadate, leaving a perfectly white residue which gave no indications of vanadium by the aniline test.

The aniline test was worked out by Witz and Osmond,[1] and is of value in estimating very small quantities of vanadium. It depends on the fact that vanadium salts are easily oxidized and reduced, and therefore can act as oxygen carriers.

If a solution of potassium chlorate is added to a solution of aniline hydrochloride, heated to boiling, and allowed to stand at room temperature, no coloration appears. If, however, a trace of vanadium is present, a color appears, varying from light yellow to black, according to the amount of vanadium present. More than a trace of vanadium will cause a precipitate of aniline black. The sensitiveness is increased by the presence of a small quantity of dilute hydrochloric acid, but a larger quantity will cause a precipitation of aniline black, even when no vanadium is present.

In making this test, a standard vanadium solution was used, containing about 0.0001 gram V_2O_5 to 1 cc.; this was used for color comparison as in the Nessler test for ammonia, and in neutral solution was about as delicate.

The time required to get all the vanadium out was about thirty hours of actual heating, and seemed to be independent of the quantity of vanadate used. The white color of the sodium chloride proved to be a very good indication of its freedom from vanadium.

---

[1] *Bull. soc. chim.*, (2) **45**, 309.

An attempt was made to use a Jena glass flask, but it cracked at a critical moment, so a quartz flask with straight neck and Jena glass inner tube was next tried. Only one experiment was completed, because the inner tube fused in contact with the quartz, when the sodium chloride was finally heated to fusion; the results of this experiment are recorded under (1) in the table. The material used was Sample A.

It was necessary to send to Germany and have two quartz flasks made of the form shown in the figure.

An advantage of the use of the quartz apparatus is that the sodium chloride could be heated to complete fusion in the vessel and all moisture thus removed. It was found that the fusion caused practically no loss by volatilization, and a quite definit weight for the salt could be obtained. The losses on heating were about as follows: The flask and salt were weighed after fusion of the salt on the edges. After complete fusion, there was a loss of 0.0012 gram. After again fusing it for several minutes to the highest temperature of the blast lamp, there was a further loss of 0.0001, or sometimes 0.0002 gram. The last weight was taken as correct. The bulb on the inner tube nearly closes the outlet to the flask, when it is held vertically, and this evidently prevents loss by volatilization.

Another quartz apparatus of the same size and shape was used as a counterpoise, the difference in weight by substitution of the flask and counterpoise being taken; on the opposit pan of the balance a quartz dish of the same weight was used as a tare. It was necessary to leave the apparatus in the balance case for several hours before the final weighing was taken. On being transferred from desiccator to balance case, the flasks seemed to lose about 0.001 gram in weight in the first hour; after that the weight would be practically constant. The loss was undoubtedly due to the fact that the flasks were filled first with the dry air of the desiccator and then with the moister air of the balance case.

After getting the final weight of the flask and fused sodium chloride, the flask was rinsed out with distilled water, heated with a blast lamp, and again weighed. The difference in weight is recorded in the table as "loss on rinsing."

On the second experiment, there was a slight increase in weight of the flask, and at the same time a slight greenish yellow coloration appeared in the neck. The yellow color remained through all the experiments; and the weight of the flask remained practically constant except in experiment IV.

In experiment IV there was a considerable gain in weight of the flask and an increase in the yellowish color on the neck. The increased color persisted until the inner surface of the neck of the vessel had been rubbed with a cloth moistened with various reagents, such as acids, ammonia and caustic potash. This treatment caused the yellow color to fade somewhat and the weight of the flask to become normal.

On heating the neck of the flask with the blast lamp, the color would travel around to the opposite side from the flame, but could not be driven away.

Our explanation is that some vanadium vapors were taken up by the quartz in the neck of the apparatus, where the heat was much less than in the body.

By taking the loss of weight on rinsing, this would not cause any error in the results.

The solution obtained by rinsing out the vessel showed a very slight turbidity which looked like silica. In one case, a few shining scales could be noticed, which evidently came from the quartz flask. This was undoubtedly due to the contraction of the fused sodium chloride on cooling; although it was spread as thin as possible, it always broke apart with considerable crackling.

The solutions obtained in the last five experiments were filtered through a small filter whose ash weighed 0 00003 gram; after ignition in a platinum crucible the weight of the silica was obtained.

Just how to apply this correction was somewhat of a puzzle. If the silica came from the quartz vessel, its loss was evidently balanced by other material absorbed, for the weight of the vessel did not decrease, and yet in one case a slight corrosion of its walls was visible. It was finally decided to assume that the silica came from the flask, and subtract its weight from the "loss on rinsing." If part of it came from the sodium vanadate, our method of correction would not be far wrong, since the silica would affect the observed weight of sodium chloride over twice as much as that of the vanadate.

In practically all cases the filtrate from the silica was tested for vanadium by the aniline test, and any trace thus indicated was subtracted from the "loss on rinsing."

The results of five experiments are given in the table in the order in which they were obtained.

Average is 50.967 ± 0.006. The atomic weights of sodium and chlorine were assumed to be 23 00 and 35 46, respectively.

The sample used in V had been the most carefully prepared of any of the series, and the amount of material used was so large that the percentage error in the weighing of the sodium chloride would be considerably diminished. So perhaps this should be given more weight in making up the average.

The experiments had to be interrupted at this point, but it is intended to make another series at some future time, using from seven to ten grams of vanadate in each experiment.

Conclusion.

This series of fairly concordant results, obtained with material prepared in several different ways, proves that sodium metavanadate is a definit and stable compound, and that it can be prepared free from excess of alkali and from acid vanadates.

The errors which would make our calculated values for the atomic weight too high are: Presence of acid vanadate, silica, or moisture in the fused sodium vanadate, and loss of sodium chloride by decrepitation or volatilization.

The errors which would make the calculated value too low are: Presence of excess of alkali in the fused vanadate, and presence of moisture in the sodium chloride.

It is hard to see how our calculated value can be too low, since correction has been applied for silica and for any vanadium remaining in the sodium chloride and the moisture must have been completely removed.

This work, in connection with that of Prandtl and Bleyer, therefore indicates that the value for the atomic weight of vanadium is about 51.0 instead of 51.2.

The writer wishes to express his thanks to Prof. W. B. Schober, of Lehigh University, for the use of the laboratory and valuable apparatus in part of this work. The valuable assistance of Mr. F. B. Kingsbury and Mr. C. A. Pierle is hereby acknowledged.

A METHOD FOR DETERMINING THE MOLECULAR WEIGHTS OF DISSOLVED SUBSTANCES BY MEASUREMENT OF LOWERING OF VAPOR PRESSURE.[1]

BY ALAN W C MENZIES

Received October 26, 1910

Among the methods available for measuring the molecular weights of substances in solution, the cryoscopic and the ebullioscopic methods are most commonly used. The method of directly measuring the lowering of vapor pressure due to the dissolved substance has not been commonly applied for molecular weight determination owing, perhaps, to the difficulty of obtaining trustworthy values of vapor pressure by the static method, even when elaborate apparatus is employed. It is proposed in the present paper to describe an apparatus and procedure by means of which, without any thermometer, molecular weights may be simply determind in the laboratory by static measurement of vapor pressure, with an accuracy at least equal to that obtained by the ebullioscopic method.

In 1858 Wullner,[2] working with aqueous solutions, found the lowering of vapor pressure roughly proportional to the concentration of the dissolved substance. The fact that workers[3] in this field confined their observations to aqueous solution of salts, which are abnormal, prevented the recognition of the underlying regularities until as late as 1886–7. Raoult's work[4] of that epoch is the basis of the present-day cryoscopic and ebullioscopic methods.

Raoult used a barometer tube, static method for measuring vapor pressures of solvent and solution. As with all static methods, chief among the sources of error are (1) the difficulty of completely eliminating gaseous and volatil impurities, and (2) the variation of the superficial concentrations of solutions due to evaporation and condensation. Even were it sufficiently accurate, Raoult's apparatus is too cumbrous for every-day use in molecular weight determination.

Air-current or air-bubbling dynamic methods for vapor pressure measurement[1] always appear promising but, perhaps on account of their inflexibility hitherto, they have not come into general use for the purpose under consideration.

After evolving his form of freezing point apparatus, Beckmann[2] turned his attention to devising a workable method of molecular weight determination by vapor pressure measurement. He discarded those methods which he tried, however, in favor of his well-known ebullioscopic method. With the benefit of the experience of these earlier workers, Biddle[3] described a vapor pressure apparatus for molecular weight determination; this, however, is somewhat complex, requires the use of a thermostat, and is applied only to the very volatil solvents, ether and carbon bisulphide.

The Apparatus.[4]—As will be seen from Fig. 1, the apparatus here proposed consists of a jacket, in which the solvent is boiled, attached to a small reflux condenser, and an inner "test-tube" furnished with a pressure gage tube and a glass stopper. The dimensions of the jacket are, length 27 cm., diameter 3.5 cm.; those of the inner "test-tube," total length 30 cm., diameter 2.3 cm. The side tube leading from the jacket to the condenser is of glass of 1 cm. bore, so that the solvent may boil under a pressure no greater than barometric. The connection may be made with an 8 cm. length of rubber tubing, furnished with a screw clip. When the glass stopper is removed and the clip closed, the vapor of the liquid boiling in the jacket is obliged to escape by blowing through the gage tube, which is open at both ends, into the test tube. The narrow (6 mm.) U-shaped side tube attached to the jacket returns the cold condensed vapor from the condenser to the lower portion of the jacket, thus avoiding chilling of the upper portion of the test tube. The latter is graduated in cubic centimeters from 15 cc. upwards, and the gage tube (diam. 5 mm.) in millimeters of length (total about 140 mm.) from above

downwards. The two sets of graduations are readable from aspects at right angles to each other, so as to avoid confusion. At its foot, the gage tube is blown into a small bulb in which are pierced a number of holes to distribute the vapor as it issues. A glass stopper, with a glass-rod handle (length 12 cm.), fits the constricted neck (diam. 12 mm.) of the test tube, while the test tube itself fits into its jacket by a ground joint. The purpose of the jacket is to maintain the test tube and its contents at a constant temperature—the boiling point of the solvent—while the purpose of the test tube is to contain the solution whose vapor pressure is being measured. The pressure measurment is made in terms of the difference of level of the solution in the gage tube and the test tube, that is, in terms of millimeters of a liquid of low density compared to mercury. Differences of pressure that are small in terms of millimeters of mercury may therefore be measured with accuracy, and this permits of the use of very dilute solutions.

The Procedure.—The procedure followed in making a molecular weight determination may properly be described in some detail. The bulb of the jacket is charged two-thirds full with the pure solvent, the empty "test tube" replaced in position, and the liquid boiled with a small naked flame for ten minutes under its reflux condenser, in order to expel dissolved gases. The flame is then removed, the test tube taken out and charged two-thirds full with the boiled-out liquid from the jacket and replaced in position with its stopper left out. The liquid in the jacket is again boiled for a minute to expel air, after which the screw-clip is closed sufficiently to cause a vigorous bubbling of vapor through the liquid in the test tube. After this "blowing-through" process has continued two or three minutes, the stopper is warmed up by inserting it obliquely in position. Vapor can still escape, but the condensed liquid collects to form several drops above the stopper. When this has taken place, the stopper is pushed home, the liquid above it serving to make the joint gas-tight, and at the same moment the screw clip is fully opened. At this stage, the temperature of the liquid in the test tube is slighly higher than the boiling point, because the liquid in the jacket has been boiling under a slightly increased pressure in order to cause the "blowing-through." The apparatus must therefore be allowed to stand for a few minutes until the temperature of the vapor chamber adjusts itself to the true boiling point of the solvent. As the jacket is clamped loosely only at its neck, the apparatus may be shaken occasionally with a jerking motion, by way of stirring.

If the dissolved gases have been removed, and if the solvent is perfectly pure and dry, the relative levels of the liquid in the test tube and gage tube will now be precisely the same as they were before the stopper was inserted; unless the solvent has been very carefully purified, however, such theoretical perfection will not be quite attained. It is obvious that the liquid in the gage tube stands somewhat the higher of the two, on account of capillarity, as shown in Fig. 2 (*a*). This reading of difference of level is taken as the zero reading, and affords an excellent test of the adequate purity of the solvent. Should the zero reading be unsatisfactory, the process of blowing-through may be repeated until at least constant results are obtained. All readings are conveniently made with the help of a small lens.

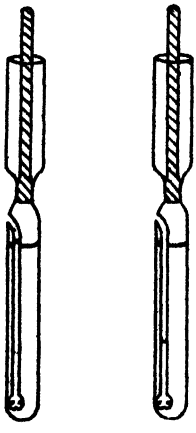

Fig. 2.

On removing the stopper, the substance may now be introduced in the form of weighed pastils, or otherwise. Solution is assisted by a gentle "blowing-through," which is necessary also to remove air. When the liquid is judged to be homogeneous and air-free, the stopper is again inserted, exactly as before, and the apparatus allowed to stand with shaking every half minute or so. At this stage the shaking, which should jerk the solution so as to wash the upper portion of the vapor-chamber walls, is very essential if surface films of abnormal concentration are to be avoided. By the circulation it causes, shaking also hastens the cooling of the central portions of the solution to the boiling point of the pure solvent. At no time, of course, must the boiling of the pure solvent in the jacket be interrupted. In about ten minutes, when the difference of level (see Fig. 2 (*b*)) after successive shakings has become constant, the reading is made and corrected by the zero reading.[1] The stopper is now removed and the volume of the solution read off, the liquid above the stopper being first removed by filter paper.

Further measurements may be made at different concentrations, either by adding more solute or else by blowing through for some time and so adding more pure solvent. Such further measurements are, however, usually unnecessary, since, with the very dilute solutions employed, the values first obtained are hardly improved by the method of extrapolation to infinit dilution.

In the case of solvents as volatil as carbon disulphide, a common test-tube filled with cold water may be inserted in the projecting upper portion of the "test tube" during the blowing-through process, if necessary to assist condensation. If, for any solvent, the rubber connection is considered objectionable, a glass stopcock[2] of large bore may take the place of the screw clip, and the use of rubber be entirely avoided.

[1] If the apparatus be allowed to stand over a couple of minutes without shaking a slow change of level appears, caused by distillation within the vapor chamber towards the stopper.

[2] To regulate more easily the passage of small quantities of vapor, notches should be filed at the sides of the holes piercing the stopper of the cock.

Calculation of Results.—From the well-known relationship

$$p - p' = P\sigma/(\rho - \sigma)$$

where, at any temperature, p is the vapor pressure of the pure solvent, p' that of the solution, P the osmotic pressure of the solution, ρ its density and σ the density of the vapor under the pressure[1] p, one may, in the case of very dilute solutions, by assuming van't Hoff's law and making the appropriate substitutions for P and σ, deduce for a barometric height of 760 mm.:

$$p - p'(\text{in mm. mercury}) = n \cdot m \cdot 760/1000\ (\rho - \sigma)$$

where n is the number of dissolved moles per liter of solution, and m is the molecular weight of the solvent in the gaseous state. In millimeters of solution partially counterpoised by vapor of density σ, this would become, if $n = 1$,

$$p - p'\ (\text{in mm. solution}) = m \cdot 760 \cdot 13.59/1000 \cdot (\rho - \sigma)^2$$

where 13.59 is the density of mercury at 0°. By assuming that $\rho - \sigma$ is equal to the density of the pure solvent[2] at its boiling point, one may thus calculate for a series of solvents the values of $K_{760} = p - p' =$ the lowering of vapor pressure in mm. of boiling solvent that would be caused by the presence of one mole of non-volatil solute in one liter of solution, the barometer being normal. The values of K_{760} for some of the common solvents are as follows:

Solvent.	Density at boiling point	K_{760}.
Benzene	0.8149	1214
Alcohol	0.7389	871.5
Water	0.9587	202.5
Chloroform	1.4101	620.4
Acetone	0.7518	1061
Ether	0.6968	1577
Carbon disulphide	1.2223	526.6
Ethyl acetate	0.8302	1320
Ethylene dibromide	1.9423	514.6

If desired, the actual value for ρ for any solution may be found directly by making a weighing of the test tube and its contents, in addition to reading off the volume of the solution, and σ may be calculated. This, however, is unnecessary for the ordinary purposes of molecular weight determination, and was not done in the examples given below.

---

[1] Should $p - \frac{p - p'}{2}$ be preferred, since with this apparatus $p - p'$ has values from about 3 to 7 mm. of mercury, the constants K would become from one-quarter to one-half per cent. smaller.

[2] At their boiling points under 760 mm., σ for carbon bisulphide, benzene, chloroform and alcohol has a value about 0.24, 0.33, 0.31 and 0.32 per cent., respectively, of ρ. If the densities of the solutions used in this apparatus exceeded the density of the pure solvent by precisely these amounts, no error would be committed by the assumption made.

The change of ρ due to a change of boiling point of the solvent caused by a barometric divergence of 10 mm. from the normal is of the order of 1 part in 1000, and is therefore negligible.

Knowing the value of K_{760} as given above, the molecular weight may be calculated from the formula

$$M = 1000\, W \cdot K \cdot B / L \cdot V \cdot 760$$

where W is the weight of solute added, L is the measured lowering of pressure in mm., V is the volume of the solution in cc., and B is the barometric height.

Examples of Results.—The table below gives examples of the results obtained with six solvents. The benzene was the crystallizable, thiophene-free product of Kahlbaum and was dried and distilled over sodium The carbon disulphide was distilled once. The alcohol, also Kahlbaum's, was dried and distilled over barium oxide. The chloroform was freed from alcohol by washing with chromic acid mixture and dried over calcium chloride. A quantity of acetone, from the disulphite compound, was distilled once with a Hempel's fractionating tube, and the first portion of the distillate taken. The solutes were also the preparation of Kahlbaum, and were used without further purification other than drying. In the table, the results of Beckmann[1] and of Walker and Lumsden[2] are added for comparison. The figures refer to the lowest and the highest concentrations which they used:

Solvent, Benzene.					
Benzil, 210.					
0.650	50.3	26.1	203.0	216–256	
Ethyl Benzoate, 150.					
0.662	53.2	90.5	164.5	163–172	

Weight of solute.	Volume of solution.	Lowering observed.	Molecular weight found.	Beckmann found.	W. & L. found.
		Solvent, Water.			
		Boric Acid, 62.			
1 201	43 0	90 7	61.6	64.6–66 9	
1.147	46 7	79.2	62.1		
1.147	46.3	81.2	61.4		
		Potassium Chloride, 74.6.			
1.001	44.8	102.2	44.2		
1.001	45.0	103.1	43.2		
1.001	45.2	102 4	43.3		

In the values found for the molecular weight, the first decimal place has been retained for purposes of comparison, but it is of little value.

Comparison with Ebullioscopic Methods.—That this method possesses greater potentialities for accuracy than the ebullioscopic method will be admitted when it is considered that an elevation of boiling point of 0.1° corresponds to a measured lowering of vapor pressure of, for example, 37, 55 and 37 mm., respectively, for water, alcohol and benzene. It should therefore be possible, with like accuracy, to employ. with this method, much more dilute solutions. This leads to the consideration of a chief source of error of the ebullioscopic methods when the more dilute solutions are employed, namely, change of boiling point due to change of barometric pressure during the experiment. To cause an error of temperature of 0.05°—fifty per cent. of the quantity measured in the case above considered—the barometer need change only 1 36 mm., 1 5 mm. and 1.2 mm., respectively, for water, alcohol and benzene. Such barometric changes affect the results of the method here described scarcely at all, since the temperature of the jacket varies proportionally, and thus automatically corrects this error. Change of barometer influences the result only by slightly affecting the constant K, which depends on absolute barometric height, as indicated above. It may be pointed out that, in the case of the ebullioscopic methods, the constant used is customarily obtained experimentally and not by calculation from theory as in the case of the method here outlined.

The time occupied in a first determination by this method may be thirty to forty minutes, including the necessary weighing. In discussing the Beckmann boiling point method, H. Biltz[1] states that 'it usually requires one hour, but often two, and sometimes, indeed, several hours, to obtain a constant temperature in the boiling vessel.' How much of this trouble is due to slow change of zero of the thermometer is difficult to say. Presumably very little, as the Landsberger type of apparatus is much more expeditious, in the form, for example, devised by McCoy.[2]

---

[1] "Pract. Methods for Determining Molecular Weights," Transl. by Jones and King, p. 155.

[2] See *Am. Chem. J.*, 23, 357 (1900).

Apropos of the thermometer, it will be recalled that a Beckmann thermometer whose degree is correct at zero is 3 6 per cent. in error[1] at 100°. Accordingly, whenever a Beckmann thermometer is employed at temperatures far from that at which its degree is correct, a correction for this error becomes necessary, although it is frequently omitted. The absence of any thermometer in the present apparatus simplifies slightly the reading of the volume of the solution; when a thermometer is present, it must first be removed.

In this apparatus, the 1 cc. graduations have a distance apart of about 2.8 mm., which makes the estimation of tenths satisfactory.

A considerable error is incident to both Berkmann and Landsberger methods when the correction for varying head of liquid above the thermometer bulb is neglected. Such an error does not here appear, for it is on the measurement of precisely such heads of liquid that the present method is based.

The use of a reflux condenser avoids the errors caused by change of temperature due to fractionation of the jacketing liquid inherent in the Landsberger method and its modifications.

The Identity of Vapor Pressure as Determined by the Static and by the Dynamic Methods.—It was tacitly assumed above that the statically determind vapor pressure of a pure liquid at its boiling point, determind dynamically, should be precisely the pressure under which the liquid boiled. In other words, it was taken for granted that if p is measured statically for any particular t, the same t will be arrived at dynamically by a boiling point measurement if p be the same. As is well known, however, it was by no means always agreed that this is the case.[2]

The apparatus here described is well adapted for testing the facts. The vapor pressure of the pure solvent in the test tube is a "static" vapor pressure, and is measured at the dynamically attained temperature of the vapor from the pure solvent boiling in the jacket. The pressure comparison is made by a differential gage of a liquid of low specific gravity, instead of, for example, by the difference of level of two mercury columns, one of which has a small depth of another liquid lying on its surface. With benzene, for instance, a pressure difference of 0.5 mm. of mercury, obtained in other methods by subtraction of much larger numbers of mm. and the application of not a few corrections, is, by this method, seen directly on a single small apparatus as a difference of level of 8.3 mm. of benzene at its boiling point (which is the manometer liquid). More important than simplicity of the pressure reading, however, is the possibility of boiling out dissolved gases until constant results are obtained; because failure to realize this possibility has been a chief cause of inconsistences in all measurements by the static method.

---

[1] *Z. Instrum.*, 1896, 202.

[2] References to the extensive literature of the controversy on this subject may be found in Ostwald's *Lehrbuch*, Vol. I, 308.

As, therefore, it seemed of interest to determin whether any small difference could be detected between static and dynamic results, the experiment was made with pure water, alcohol and benzene. The following figures refer to benzene, which had recently been distilled over sodium, but was not boiled out in the jacket. The differences of pressure, Δp, are in mm. of benzene at its boiling point, while the times, T, refer to the number of minutes of the "blowing-through" process:

Δp	6 3	2 5	0 9	0.1	0.1
T	5.0	6 0	8 0	10.0	12.0

The zero reading was that found when the stopper was removed. It will be seen that the difference of pressure finally observed was not larger than the limits of the error of observation.

It was shown in a similar way that, if any difference exists between the vapor pressure at the boiling point as measured dynamically and statically of the liquids water and alcohol, then such difference does not exceed 0.01 mm. of mercury.

Purpose and Scope.—In the present paper, the purpose has been to describe a molecular weight apparatus and its every-day application in cases where the greatest refinement is not aimed at. When opportunity offers, it is proposed to carry the measurements to their highest accuracy, and to make such applications of the method as promise to be most productive.

[Communications from the Laboratories of General and Physical Chemistry of the University of Chicago.]

A CONVENIENT FORM OF APPARATUS FOR THE MEASUREMENT OF THE VAPOR DENSITIES OF EASILY VOLATIL SUBSTANCES.[1]

By Alan W. C. Menzies.

Received October 26, 1910

By the very slight modification here explained, the apparatus described in the preceding paper may be simply adapted for the rapid and accurate measurement of vapor densities of easily volatil substances.

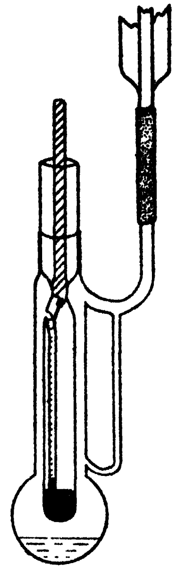
The principle employed is that of the measurement of the increase of pressure that occurs when a known weight of substance is introduced into a closed vessel at constant temperature, high enough to completely volatilize the substance.[2]

The Modification Required.—The closed chamber is provided by the "test-tube" of the former apparatus, which is the inner tube in the figure. This is closed below by pouring in from six to eight cc. of mercury. This mercury serves at the same time the purpose of manometer liquid, indicating by its rise in the graduated narrow gage tube the increase of pressure within the test tube.

---

[1] Read before the American Chemical Society, July 15, 1910.

[2] For other work in this field cf. Gibson Dyson, *Chem. News*, 55, 88 (1887); Bleier and Kohn, *Monatsh.*, 20, 909; 21, 575; Lumsden, *J. Chem. Soc.*, 83, 342; Blackman, *Chem. News*, 100, 13; etc.



The substance is weighed off in bulblets whose attached capillaries, 2–3 cm. in length, are sealed off before the final weighing. In order to attach the bulblet to the stopper of the test tube, the latter must be provided with a hole of about 1.5 mm. diameter and 5–6 mm. length. This hole may be drilled in the glass stopper, or else *added* by fusing to the lower end of the stopper a short length of thick-walled tubing of 1.5 mm. bore. The point of the bulblet's capillary can now be fixed in this hole by stuffing with a few shreds of dry asbestos. The hole should be oblique, in order that the neck of the bulblet may be broken by rotating the stopper in such a way that the bulblet is forced against the top of the gage tube (see figure). It is evident that the presence of this small hole in no wise unfits the apparatus[1] for its original purpose.

The Procedure.—The bulb of the outer jacket is charged one-third full with a liquid of suitably high boiling point, which is caused to boil steadily, the vapor thus serving to jacket the whole of the closed portion of the test tube. It is most convenient in practice to find a constant for the apparatus, at the temperature used, by volatilizing a known weight of a standard liquid, such as benzene, rather than to calculate the vapor density from measurements of the volume of the closed chamber and of the temperature. A quantity of benzene suitable to give a rise of mercury level of about 100 mm. is, therefore, sealed and weighed in a bulblet. The smaller the bulblet that will hold the requisite quantity of liquid, the better. The neck of the bulblet is then prepared for easy breaking by one or two scratches from a file. The tip of the capillary is inserted in the hole in the stopper, and the latter, after suitable lubrication, placed cautiously in its position. As the air surrounding the cold bulblet becomes warmed, the mercury rises a few mm. in the gage tube and in 5–6 minutes has reached a constant level, which is read off on the engraved scale of mm. Its position is shown in the figure. The stopper is now rotated so as to snap the neck of the bulblet, which falls on to the surface of the mercury. At the same instant the mercury in the gage tube shoots up, and reaches a constant level in a few seconds. The amount of rise is observed, and is corrected by adding the amount of the simultaneous slight fall of mercury level in the test tube.[1] From the three data (1) weight of benzene taken, (2) known molecular weight of benzene, (3) rise in mm., is calculated a constant for the apparatus, *K*, which is the rise in mm. that would be caused by the volatilization of one gram-molecular weight of any substance in this apparatus at this temperature. Having obtained this constant, the unknown molecular weight of any substance may be calculated by substituting the measured rise, *R*, and weight taken, *W*, in the formula

---

[1] The apparatus, with the modified stopper, may be had from the Central Scientific Co., 349 W. Michigan Street, Chicago, Ill.

$$M = W \cdot K / R.$$

After each measurement, the stopper is removed and a current of air aspirated through the test tube for a few seconds by introducing into it the end of a tube connected with the water pump. Several of the broken bulblets may be allowed to accumulate in the apparatus.

Examples of Results.—The measurements recorded below, including the time necessary for the weighings and for finding the constant of the apparatus, were completed in a period of three hours. The jacket contained boiling toluene. The substances whose molecular weights are determined were the preparations of Kahlbaum, each dried and purified by distillation. The chloroform was previously freed from alcohol by washing with chromic acid mixture. Every result obtained is given:

Substance.	Weight taken.	Rise in mm.	Log. *K*.	Molecular weight.	
				Found.	Normal.
Benzene....	0.0238	16.5	5.5820	..	78.05
	0.0205	100.5	5.5827	....	....
Ethyl iodide....	0.0429	104.7	5.5824	156.7	156.0
	0.0328	80.5		155.8	...
Carbon disulphide...	0.0262	132.1	...	75.8	76.1
	0.0180	90.7	....	75.9	....
Chloroform........	0.0312	99.9	....	119.4	119.4
	0.0347	110.0	...	120.6	....
Methyl iodide......	0.0328	87.4	....	143.6	141.9

For the following determinations, I am indebted to Mr. R. D. Mullinix, who was without previous experience of vapor density measurements by any method, and who, indeed, first learned to weigh accurately in order to make these determinations. The jacket contained commercial xylene, b. p. 137.8°. Every determination made by Mr. Mullinix, other than his preliminary ones, is recorded:

---

[1] The value of this correction for a given rise of mercury in the gage tube having been determined once, the values for other cases are thereafter obtained by simple proportion.

As an example of the application of this apparatus to a special problem, the percentage composition of a binary mixture of substances of known molecular weight may be found. For this purpose, the solubility of carbon disulphide in methyl alcohol was determined at 22.2°. The average molecular weight of the upper layer obtained on mixing these liquids was found to be 52.5, which would give a percentage of carbon disulphide of 53 4. Interpolation from the data of Rothmund[3] would lead to 52.3. In cases of this kind, other analytical methods are sometimes troublesome.

Remarks on the Method.--The apparatus is considerably more compact than the Victor Meyer form, and stands at a convenient level above the working bench. It is very simply set up, requiring a single ring stand with two clamps, one of which holds the condenser.

If a constant be determined as suggested, correction is, of course, not necessary for the density of mercury or for its vapor pressure. If a record be kept of the volume of mercury employed, the constant need not be redetermined when the apparatus is next used.

---

[1] At normal pressure, chlorobenzene boils at 132°. The temperature of the jacket was 137 8°. As the pressure within the closed chamber increases, the volatilization of the chlorobenzene from the bulblet becomes rather slow.

[2] It will be seen that the values obtained for acetic acid, whose vapor is known to be associated, differ little from the monomolecular value. It must be recalled that, in this apparatus, the partial pressure of acetic acid vapor in the closed chamber is less than one-seventh of an atmosphere.

[3] *Z. physik. Chem.*, **26**, 475.

Correction for change of jacket temperature due to barometric change is negligible. Thus, 23 mm. change of barometer causes a change of 1° in the boiling point of toluene (384° absolute), or 1 part in 384 in the result.

When the final level of the mercury in the gage tube is very different from that measured in finding the constant of the apparatus, it is plain that the gas content of the test tube will be somewhat different. Correction for this is usually unnecessary, and was not made in the above examples.

As every portion of the enclosed chamber is kept at the constant high temperature, there is nothing to be feared from the diffusion of the vapor to colder parts of the apparatus, as in the case of the Lumsden or Victor Meyer apparatus. Thus, Lumsden remarks:[1] "The accuracy of the results depends very much on the rapidity with which the substance is vaporized, and this is the more important the smaller the molecular weight, since a vapor which diffuses rapidly may reach the colder part of the apparatus before a measurement of pressure can be made." Again, as no air is driven from a hotter to a colder place, no uncertain correction on this account has to be considered.[2]

Since the vapor is likely to be diffused throughout the whole of the test tube, and since the pressure read is less than one-sixth of an atmosphere, the partial pressure of the vapor cannot even locally much exceed one-sixth of an atmosphere. This low pressure lessens any tendency to association, as is seen in the acetic acid example given above. It is obvious that the test tube may be filled with an inert gas if desired.

Instead of a glass stopper, a one-holed rubber cork may be used at the lower temperatures. A glass rod, bent for the lowest centimeter of its length, passes through the hole, and by its timely rotation breaks the neck of the bulblet, which is inserted into a small blind hole beside it, and is pressed against the top of the gage tube. This form of "release" is perhaps easier to operate than that described above.

In the form described, this apparatus is not suitable for temperatures above 200°; but the examples given seem to show that it is both rapid and accurate for use at temperatures at which it is applicable.

RAPID DETERMINATIONS AND SEPARATIONS BY MEANS OF THE MERCURY CATHODE AND STATIONARY ANODE.

BY R. C. BENNER AND M. L. HARTMANN.

Received October 11, 1910.

The mercury cathode has been used for most metals which can be determined electrolytically. In the case of bismuth it is possible to make the determination with greater ease by this method than with platinum electrodes. The determination of chromium, while impossible by ordinary electrolytic methods, can be thus accomplished.

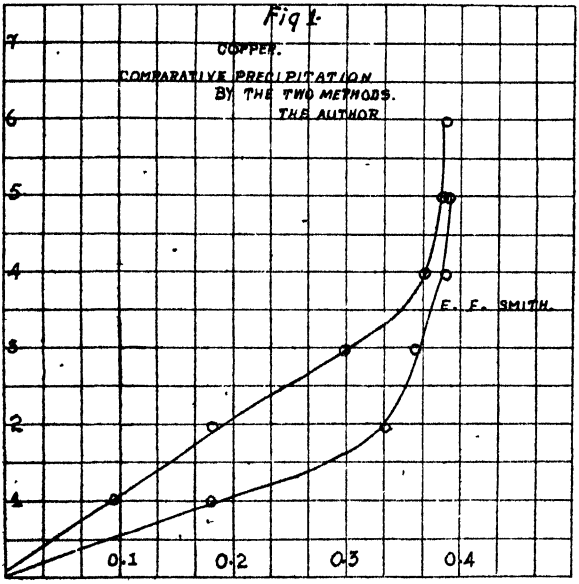
---

[1] *Loc. cit.*

[2] Cf. T. W. Richards, *Chem. News*, 59, 87.

The mercury cathode has been used with a stationary anode and low currents, as well as with the rotating anode and high currents, but not until recently has it been proven possible to use the stationary anode and high currents without some means of mechanical agitation.[1]

In order to determin what time could be saved by the use of the rotating anode, the rate of precipitation was determined without agitation under the same conditions as those used by Smith.[2] The curves in figures 1 and 2 show, that while the precipitation of copper and silver is more rapid when the rotating anode is used, the difference is not nearly as great as would be expected. This lack of rapidity is, moreover, much more than compensated for by the simplicity of the apparatus in case of the stationary anode.



It is possible to precipitate:

(1) 0.2075 gram of iron in 10 minutes with three to four amperes when the rotating anode is used.

(2) 0.1000 gram in the same time with four amperes when the solution is rotated by means of the solenoid.

(3) 0.2007 gram in 20 minutes with the stationary anode and four

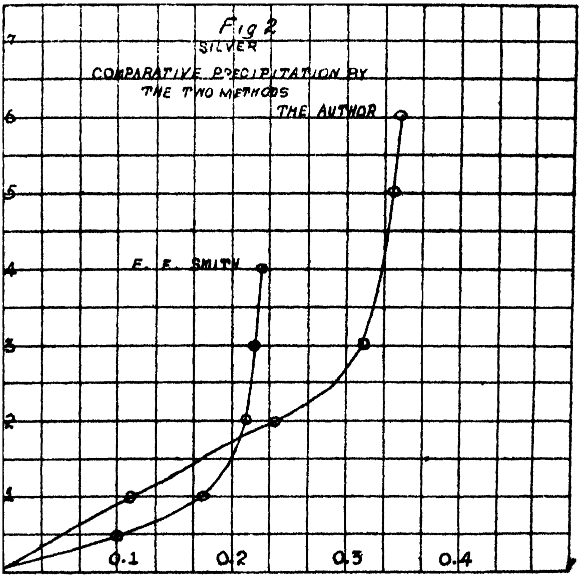
amperes. Therefore, although there was no means at hand for making a direct comparison between this method and that in which the electrolyte was rotated by means of a solenoid,[1] it would seem that there is little, if anything, to be gained from magnetic rotation.



The following determinations and separations were carried out using the apparatus of our previous article.[2]

Nickel.—For the determination of nickel a solution of C. P. nickel sulphate was prepared and the nickel determined electrolytically.[3] It was found to contain 0.1089 gram of metallic nickel per 10 cc.:

0.1089	0.1080	− 010009	4–5	9–10		20	0.2228

Reference to the table shows that with currents varying from three to six amperes, at seven to ten volts, it is possible to make accurate determinations of nickel, from a sulphate solution, either in the presence of from two to ten drops of sulphuric or four to six drops of nitric acid, when one or two drops of sulphuric acid are present, in 10 to 20 cc. of the electrolyte. The precipitation is sufficiently rapid for all practical purposes, as it is possible to precipitate 0.2178 gram of nickel from 20 cc. of solution in 8 minutes (Fig 3).

The determination of nickel in the presence of aluminium, titanium and the rare earths in a sulphuric acid solution, under the same conditions as were used for its determination alone, is as rapid and as accurate as when they are not present.

Cobalt.—A solution of cobalt sulphate was prepared from C. P. cobalt sulphate and made acid by the addition of a few drops of sulphuric acid. Ten cc. of the solution were found, by the electrolytic method,[1] to contain 0.1041 gram of metallic cobalt.

Cobalt taken.	Found	Error	Amperes.	Volts	Drops of acid. H_2SO_4	Volume.	Time.

0.1041	0.1042	+ 0.0001	3-4	6-7	1	10	12
0.2082	0.2081	- 0.0001	3-4	6-7	1	20	..
0.2082	0.2085	+ 0.0003	3-4	6-7	1	20	.
Rate of Precipitation of Cobalt (Fig 4).							
0.3516	0.1885		5	6-7	1	20	3
0.3516	0.3039		5	6-7	1	20	6
0.3516	0.3428		5	6-7	1	20	9
0.3516	0.3510		5	6-7	1	20	12
0.3516	0.3512		5	6-7	1	20	15

The determinations given in the table were carried out in solutions containing from 0.05 to 0.1 cc. of sulphuric acid and with currents varying from three to six amperes, at 6 to 12 volts. This gave complete precipitation of 0.1041 to 0.3516 of a gram of cobalt in from 10 to 15 minutes (Fig. 4). Results were good from weak sulphuric acid but not from strong acid solutions or those containing nitric acid.

Zinc.—A standard solution of zinc was prepared by dissolving a weighed amount of C. P. metallic zinc in sulphuric acid and diluting so that 10 cc. of the solution contained 0.2980 gram of metallic zinc and 0.3 cc. of sulphuric acid.

It was found that by carrying out the determination of zinc in a manner similar to the previous determinations of the other metals, it was possible to deposit zinc quantitatively either from solutions of the sulphate containing sulphuric acid or with nitric acid in the presence of a little sulphuric acid. The deposits were made with currents varying from three to six

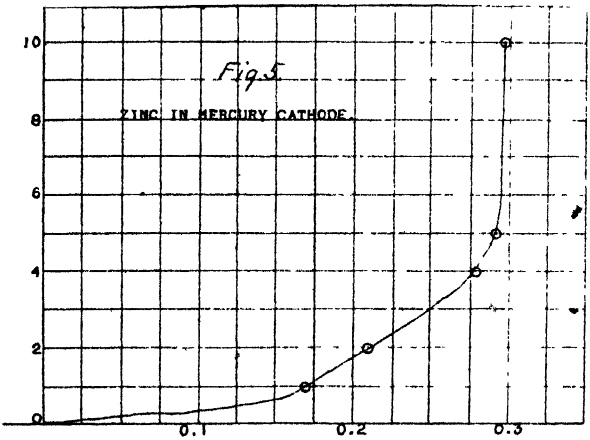
Using the same conditions as in the determination of zinc, it is possible to separate zinc from aluminium and titanium without difficulty.



Iron.—The standard solution of iron was made by dissolving a weighed amount of ferrous ammonium sulphate in water and making acid with sulphuric acid to prevent the formation of basic iron sulphate. Ten cc. of this solution contained 0.1002 gram of metallic iron and 0.11 cc. of sulphuric acid. Iron was determined with the usual apparatus by means of currents varying from 3–4 amperes at 7–8 volts. Solutions containing either nitric or sulphuric acid were used with very satisfactory results. The rate of precipitation with the mercury cathode is slower than that for most metals, it being possible to deposit in twenty minutes only 0.2004 gram of iron, from 20 cc. of solution, with a current of four amperes (Fig. 6).

The separation of iron from aluminium, titanium, the rare earths of the cerium and yttrium groups as extracted from monazite, was tried under the same conditions used for the determination of iron, with satisfactory results.

The exact variation of conditions can best be seen from the table given above.

Conclusion.

(1) Comparison of the rates of precipitation under like conditions of current, volume of solution, etc., shows that, although the rate of precipitation with the rotating anode is greater than with the stationary anode, it is not sufficiently so to recommend the use of so much more complex a piece of apparatus.

(2) The results obtained by this method are as accurate as those obtained by means of other mercury cathode methods.

(3) With the different metals determined it is possible to use about the same conditions as for the determination by means of the rotating anode and the mercury cathode.

Introduction.

In a paper published in 1909,[1] the hypothesis of Sir J. J. Thomson, according to which the linkages between atoms in a compound are caused by the transfer of corpuscles,[2] was applied to a number of facts drawn chiefly from organic chemistry. An attempt will be made in this paper to develop the subject somewhat farther. The same fundamental hypothesis, in the sense of a "supposition which it is expected will be useful" will be used. The deductions which will be made from this fundamental hypothesis are not put forward as the only explanation of the phenomena in question but as a possible explanation simpler in some ways in correlating facts than some of the explanations in current use, and in a few cases offering explanations for facts which have not been explained heretofore. The isomerism in compounds containing a double bond may serve to illustrate the former and the physical properties of the saturated dibasic acids the latter.

[2] "The Corpuscular Theory of Matter," pp. 138–9 (1907).

1. Limitations of the Problem.

The valence of an element may be defined as a number which shows how many unit atoms or groups (with the hydrogen atom as unit standard) may be held in combination by an atom of that element. These valence numbers are purely the result of experimental investigations, but have been correlated to a great extent by the Periodic Law from which may now be taken the maximum valence of an element. The problem to be taken up here is limited by a clear conception of valence and the hypothesis to be used later. It may be stated, however, that stability relations of compounds, isomeric and otherwise, can enter only qualitatively in the discussion of valence since quantitative results can be arrived at by the use of the free energy relationships alone.

A valence theory, to be acceptable, must include or be able to account for all compounds known. The fact that the compounds predicted or suggested by the theory are not known would also be less disadvantageous for the theory than if compounds were known for which the theory was not able to account. This non-existence of compounds predicted by a theory may be due to the very limited range of conditions under which most of the substances known at present have been prepared.

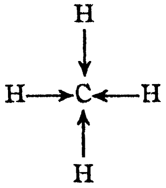
The subject of valence will not be taken up historically. Some or many of the ideas to be treated have been given before, but the work of those who have treated of this or of closely related subjects as for instance Abegg, and W. A. Noyes, will not be taken up in detail. It may be stated, however, that the scope of the subject matter and its treatment is different from that which has been given by others.

2. Fundamental Hypothesis.

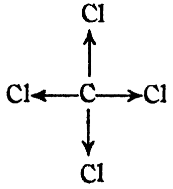
The hypothesis of Sir J. J. Thomson which will be elaborated here may be stated most concisely in his own words. "For each valency bond established between two atoms the transference of one (negatively charged) corpuscle from the one atom to the other has taken place, the atom receiving the corpuscle acquiring a unit charge of negative electricity, the other by the loss of a corpuscle acquiring a unit charge of positive. This electrical process may be represented by the producing of a unit tube of electric force between the two atoms, the tube starting from the positive and ending on the negative atom. . . . There is, however, one important difference between the lines representing the bonds and the tubes of electric force. The lines used by the chemist are not supposed to have direction. . . . On the electrical theory, however, the tubes of electric force are regarded as having direction starting from the positive and ending on the negative atom. . . . " This hypothesis supplements the structural formulas employed at present by giving the bonds direction. For convenience the lines which heretofore represented the bonds may be replaced by arrows, the direction of the arrows indicating the direction of the transfer of the corpuscles. Two atoms united in this way possess opposite electric charges. In regard to the direction of the valence when two atoms combine it seems fair to assume that this direction is ordinarily determined by the relative positions of the elements in the Periodic System. Namely, in the horizontal rows the elements of higher atomic weights are normally negative to the elements of smaller atomic weights. In the same vertical series, the main and subgroups must be considered separately, but on the whole the relations are fairly obvious here as well. This refers to the direction of the valences normally, but in certain cases the reverse direction may exist for a less stable form of a substance having the same composition. Thus, two forms of iodine chloride exist, which may be formulated $I \longrightarrow Cl$ and $I \longleftarrow Cl$, the presumption being that the former represents the stable form. Difficulty may also exist in assigning directed valences to compounds containing a number of linked carbon atoms, since the carbon atom appears to be able to take up a corpuscle or lose one with equal readiness. The inertness of carbon compounds in general also makes it more difficult to draw conclusions as to their structure and relative stabilities.

3. Carbon Compounds Containing Single Bonds.

In taking up the compounds of carbon containing single bonds, the introduction of directive valence will not be of much value since the chemistry of these compounds is worked out fairly completely and satisfactorily without it. It may be of interest, however, to call attention to some points. As examples, it may first be mentioned that, as J. J. Thomson points out,[1] methane and tetrachloromethane might be represented by the formulas:

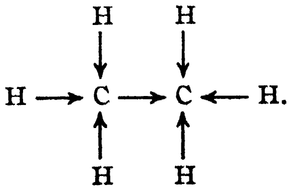


$$\begin{array}{c} H \\ \downarrow \\ H \rightarrow C \leftarrow H \\ \uparrow \\ H \end{array}$$



$$\begin{array}{c} Cl \\ \uparrow \\ Cl \leftarrow C \rightarrow Cl \\ \downarrow \\ Cl \end{array}$$

The carbon atom in methane has gained four corpuscles, while that in tetrachloromethane has lost four. Ethane is represented by the formula



$$\begin{array}{ccccccc} & & H & & H & & \\ & & \downarrow & & \downarrow & & \\ H & \rightarrow & C & \rightarrow & C & \leftarrow & H. \\ & & \uparrow & & \uparrow & & \\ & & H & & H & & \end{array}$$

---

[1] *Loc. cit.*, p. 131.

In ethane, therefore, one of the carbon atoms will have a charge of four units of negative electricity and the other of two units, or comparing the carbon atoms of the two methyl groups, one will be negatively charged, the other positively. With ethane there is no evidence as to whether such a condition exists, but it may apply in the case of hexaphenyl ethane. Thus if Gomberg's triphenyl methyl is assumed to be hexaphenyl ethane, then the two triphenylmethyl groups composing it would be charged differently, and it is an interesting fact that solutions of the substance conduct the electric current[1] and that Gomberg early in his investigations explained this by assuming the existence of the "pseudoions" $(C_6H_5)_3C^+$ and $(C_6H_5)_3C^-$.

In the solid state, then, hexaphenylethane, colorless, would be present; in solution, the colored ions exist, and are more reactive than the unionized organic compound, as is generally the case. The same is true of the triphenylmethyl halides. The application of this view to the substances related to triphenylmethyl recently described by Schlenk[2] is obvious.

The saturated dicarboxylic acids may also be taken up briefly. In malonic acid the arrangement of the groups may be represented by $(CO_2H) \longleftarrow CH_2 \longrightarrow (CO_2H)$, the molecule being symmetrical. In succinic acid, the arrangement would be $(CO_2HCH_2) \longrightarrow (CH_2CO_2H)$,—unsymmetrical; in glutaric acid, $(CO_2HCH_2) \longleftarrow CH_2 \longrightarrow (CH_2CO_2H)$,—symmetrical; in adipic acid, $(CO_2HCH_2CH_2) \longrightarrow (CH_2CH_2CO_2H)$, or unsymmetrical; in pimelic acid, symmetrical again, and so on. These acids would therefore fall into two groups—those with an even number of carbon atoms having unsymmetrical directive valences, and those with an odd number of carbon atoms having symmetrical directive valences, and the acids of each group would be strictly homologous only with the acids of the same group. The fact that the saturated dibasic acids differ in properties depending upon whether an even or an odd number of carbon atoms is present is a well-known one and is spoken of in all text-books of organic chemistry. Thus the acids containing an even number of carbon atoms have higher melting points and smaller solubility than the acids with an odd number of carbon atoms immediately preceding and succeeding them, but show regularities when compared with the next acids with an even number of carbon atoms. These relations are accounted for when directive valences are considered. It is probable that similar relations apply to the saturated monobasic acids, but the direction of the valences cannot be shown as yet with sufficient certainty in their cases.

4. Carbon Compounds Containing a Double Bond.

In taking up compounds of carbon containing a double bond, it is not possible to make any simple assumption regarding the direction of the valence when two groups combine, as was done with the singly bonded substances. It is necessary to consider all the possible cases and from a study of the reactions decide which formula may be assigned to a given compound.

The compounds containing a double bond may in general be divided into two classes: (1) compounds in which the two halves of the molecule are similar; and (2) compounds in which the two halves of the molecule are dissimilar. To the first class belong the substances of the general types $CR_2 : CR_2$ and $CRR' : CRR'$. Introducing the conception of directive valence, it is evident that there are possibilities of the existence of two isomers in each case; that is, the two valences (or corpuscles) may proceed from one carbon atom to the other, or one may proceed in one direction and one in the other;[1] or formulated as follows: $CR_2 \rightleftarrows CR_2$ and $CR_2 \rightrightarrows CR_2$; $CRR' \rightleftarrows CRR'$ and $CRR' \rightrightarrows CRR'$. If two isomers exist in any case, one would be expected to be more stable than the other; if only one substance of the general type exists, then it may be that the other is too unstable to be formed permanently, going over into the stable form, and it would be a question then, to determin by means of the chemical reactions of the substance, to which of the two types its reactions show it to conform best.

Of substances derived from the type $CR_2 : CR_2$ none is known to exist in two forms.

Thörner and Zincke[2] observed the formation of a hydrocarbon melting at 243–4°, on heating α-benzopinacolin with soda lime at a temperature of 350–80°. They thought, from its composition, that it might be identical with tetraphenylethylene, even though it showed a higher melting point. On account of these observations of Thorner and Zincke it seemed worth while to test the possible existence of more than one form of tetraphenylethylene But in no case have the results confirmed this supposition.

Some of the methods tried to bring about the transformation of tetraphenylethylene consisted in heating the alcoholic solution of the substance with both alkali and acids, and with rapid and slow cooling of the solution for the subsequent crystallization and also cystallizing in the dark as well as in the direct sunlight. In place of acids or alkali, iodine was used in a similar way, but tetraphenylethylene was again obtained having the original melting point. Next tetraphenylethylene was heated above its melting point and then suddenly chilled and it was also distilled and the distillate suddenly cooled, but no change was observed.

---

[1] In those cases where one valence proceeds in one direction and one in the other it is assumed that the corpuscles which are transferred are localized on the atoms, as otherwise the carbon atoms would become electrically neutral, but no assumption is made as to their relative positions except for the one case where four unlike atoms or groups are combined, when the phenomena of optical activity demonstrate that the four directions of valences do not lie in one plane. This localization is tacitly assumed in all cases.

[2] *Ber.*, 11, 1396 (1878).

Tetraphenylethylene was also prepared by different methods, such as heating dichlorodiphenylmethane with diphenylmethane in a sealed tube for two days at 300°. Tetraphenylethylene was obtained in this way, but with much greater difficulty than where the two halogens are on different carbon atoms, as in case of mono-homo-diphenyl methane which yielded tetraphenylethylene very easily and is the method generally employed for its preparation. Tetraphenylethylene was also obtained in small amounts by heating benzophenone and diphenylmethane in the presence of phosphorus pentoxide. In both of the above methods, however, the melting point of the tetraphenylethylene was 220°. As a conclusion from these experiments it seems highly improbable that there exists an isomeric tetraphenylethylene.

The direction of the valences in the compounds of this group might be determined by following some of the addition reactions of closely related compounds. Since the molecule is perfectly symmetrical, it makes no difference in the resulting compound, in which way another substance, HI for instance, is added. If, however, as a typical example, propylene $CH_3.CH:CH_2$ is taken, there would be three possibilities: $MeCH \rightleftarrows CH_2$ and $MeCH \rightrightarrows CH_2$ or $MeCH \leftleftarrows CH_2$. On treating with HI, if either of the last two represents the structural formula, the I would all go to one carbon atom, and the H to the other, only one substance being formed; while if the first represents the structure, a mixture of two substances should be formed, the H and I being divided between the two carbon atoms. The reactions in this case might be represented as follows:

$$MeCH \underset{H \longrightarrow I}{\rightleftarrows} CH_2 = MeCH_2 \longrightarrow CH_2I \text{ and } MeCH \overset{I \longleftarrow H}{\rightleftarrows} CH_2 = MeCHI \longleftarrow CH_3.$$

The extent to which each of the products would be formed would depend upon the influence of the methyl group as compared with the hydrogen or the double bond, and upon the difference in polarity between the hydrogen and iodine; the smaller the difference the more nearly equal would be the amounts of the two products formed.

The following results were obtained by A. Michael:[1]

Propylene + HI formed principally $(CH_3)_2CHI$ together with a little $C_2H_5CH_2I$.

Propylene + ClBr yielded 5 parts $CH_3.CHBr.CH_2Cl$ to 7 parts $CH_3.CHCl.CH_2Br$.

Propylene + ClI yielded 1 part $CH_3.CHI.CH_2Cl$ to 4 parts $CH_2.CHCl.CH_2I$.

Propylene + HOCl formed principally $CH_3.CHOH.CH_2Cl$ and perhaps a little $CH_3.CHCl.CH_2OH$.

These examples have been quoted in order to throw some light, if possible, upon the direction of the valences in unsaturated compounds existing in one form, and they indicate that this form has the structure $CR_2 \rightleftarrows CR_2$. Propylene does not belong to this type of compound; but it seems fair to carry over the conclusions arrived at with propylene to the symmetrical compounds and to assign this structure to the substance, if only one form exists, and if two forms exist, to assign it to the more stable of the two.

---

[1] *J. prakt. Chem.*, 60, 286–384, 409–86 (1899).

Of substances derived from the type $CRR':CRR'$ a large number of isomers are known, of which maleic and fumaric acids may serve as examples. The two forms of this type using the directive valences are $CRR' \rightleftarrows CRR'$ and $CRR' \rightrightarrows CRR'$ of which the former represents the more stable, the latter the less stable form. These two groups of substances belong to the fumaroid and maleinoid types, the fumaroid being the more stable, showing the higher melting point, less solubility and volatility, smaller heats of combustion, less color (if any is shown by either isomer), and, in the case of acids, smaller ionization constants than the maleinoid, all these properties being only different expressions for the difference in stability between the two forms. It will hardly be necessary to enter into a detailed description of the different substances included in this class. The possibilities of addition would be worked out in each case by the method indicated with propylene.

With the substances containing a double bond in which the two halves of the molecule are dissimilar, there are a greater number of possibilities, namely, $CR_2:CRR'$; $CR_2:CR'_2$; $CR_2:CR'R''$; $CRR':CR'R''$; $CRR':CR''R'''$. In each of these cases, using directive valences, there would be three isomers possible, one valence acting in each direction, both valences acting in one direction, and both in the opposite direction. The three possible isomers corresponding to these are not known for any one substance with certainty. The reason for this may be found in the fact that if the two halves of the molecule are made up of groups differing very much in properties, of the two isomers in which both valences act in the same direction, one will exhibit very much greater stability than the other, making it extremely difficult, if not impossible, to isolate the less stable form.

With regard to the cinnamic acids, it appears advisable at present to delay the application of directive valences until the properties of the isomers have been studied sufficiently in the solid and liquid states as well as in solution to allow of more definit characterization of each form than is possible at present.

The reaction described by Michael and Bunge,[1] according to which both the fumaroid and maleinoid crotonic acids add chlorine either in sunlight or the dark to form the same maleinoid dichloride can readily be accounted for with directive valences.

[1] *Ber.*, 41, 2907 (1908).

The application to benzene and some of its derivatives is obvious, but will not be enlarged upon here.[1]

Note added November 12.—Stobbe and Wilson[2] prepared three forms of the para- and of the meta-nitrobenzaldeoxybenzoin and showed that they are true isomeric chemical compounds. The existence of the three forms can be accounted for with directive valences as described, but the structure to be assigned to each form is as yet uncertain.

5. Carbon Compounds Containing a Triple Bond.

With regard to carbon compounds containing a triple bond, there are evidently many possibilities in the way of drawing formulas involving directive valences, most of which are entirely unnecessary, if not actually incapable of realization, at the present time, since very few, if any, isomeric compounds of this kind are known. It may be shown, however, that the stable form of triple-bonded compounds is in all probability best represented by the structure $RC \underset{\longleftarrow}{\overset{\longrightarrow}{\longrightarrow}} CR'$. Taking acetylene dicarboxylic acid, perhaps the simplest example which could be chosen, treatment with 10 per cent. hydrobromic acid at ordinary temperatures for five days yielded bromofumaric acid, the conditions being such that bromomaleic acid would not be transformed into bromofumaric acid.[3] The same was found in the case when hydrochloric acid was used. The reaction here is

$$(CO_2H)C \underset{\longleftarrow}{\overset{\longrightarrow}{\longrightarrow}} C(CO_2H) + HBr = (CO_2H)BrC \underset{\longleftarrow}{\longrightarrow} CH(CO_2H).$$

Bromine and acetylenedicarboxylic acid yielded 30 per cent. dibromomaleic acid and 70 per cent. dibromofumaric acid. Considering the structure of acetylenedicarboxylic acid,

$$(CO_2H)C \underset{\longleftarrow}{\overset{\longrightarrow}{\longrightarrow}} C(CO_2H),$$

and the reagent bromine, it is evident that there is the same chance or tendency of addition to each of the three bonds, or that one-third of the compound would be transformed into

$$(CO_2H)BrC \underset{\longrightarrow}{\longrightarrow} CBr(CO_2H)$$

and two-thirds into $(CO_2H)BrC \underset{\longleftarrow}{\longrightarrow} CBr(CO_2H)$.

6. Relative Asymmetry.

The introduction of directive valence into organic formulas does not affect the view of the tetrahedral form of the carbon atom in so far as this applies to single bonds. This view only requires that the four valences do not act in one plane.[4] The case is different, however, for the double-bond isomerism. Without going into the advantages and disadvantages of the theory of "geometrical isomerism," it may be pointed out that directive valences afford an explanation for the existence of isomers which does not involve the spatial relations between the groups at all but refers the isomerism to the double linkage between the atoms.

[1] This has been done in the preliminary paper, pp. 187–8.

[2] *Ann.*, **374**, 237 (1910).

[3] Michael, *J. prakt. Chem.*, [2] **46**, 210 (1892).

[4] It may be pointed out that the existence of the third active malic acid (Crassulaceen-malic acid) may be explained by the direction of the valence between the central carbon atoms (for the properties of this acid cf. Werner, *Lehrbuch der Stereochemie*, p. 114).

The subject of relative asymmetry which appears to involve both the tetrahedral model and geometrical isomerism remains to be considered.

Without entering into the details of the question, it may be stated that if "pseudoasymmetry" be extended to those cyclic compounds for which the explanation of relative asymmetry has been used, the experimental facts will permit of explanation without involving the position of the groups on one side or the other of the ring.[1] This has been pointed out by A. W. Stewart in his book on "Stereochemistry"[2] in which he states that "relative asymmetry" is only a special case of "pseudoasymmetry."

7. Nitrogen Compounds Containing a Single Bond.

The study of the compounds of nitrogen in which directive valence (or transfer of corpuscles) takes the place of the usual method of linkage between the atoms may be pursued in the same way as with the compounds of carbon. The nitrogen atom has the power of taking up three corpuscles, as shown by ammonia, or of losing five. The latter cannot be seen directly since the compounds of nitrogen with the univalent elements capable of taking up corpuscles (namely, the halogens) are unstable under ordinary conditions, but is evident from the compounds of nitrogen with oxygen. The difference between the two extreme states of nitrogen would be eight units of valence, or the nitrogen in ammonia differs from the nitrogen in nitric acid by eight corpuscles. The difference in the direction of the valence (or the loss or gain of corpuscles) can be followed much more readily with the nitrogen than with the carbon compounds, since a more evident difference in the properties of the compounds results, making it fairly easy to follow a given nitrogen atom containing a certain charge through a series of compounds and their derivatives. Nitrogen in addition to being able to take up three corpuscles is able to take up a fourth, if at the same time one is also given up, ammonium compounds being formed.[3] With the compounds of nitrogen, just as with carbon, if an element or group is joined by means of a single bond, this bond may be assumed to have a definit direction depending upon whether the element or group is electronegative (capable of taking up a corpuscle) or electropositive (capable of giving up a corpuscle) toward the nitrogen. A possible exception to this may be quoted from an article by Meisenheimer,[1] in which he considered it probable that in methylethylphenylhydroxyl ammonium hydroxide, the two hydroxyl groups are united to the nitrogen by unequal valences.

---

[1] For the development of "pseudoasymmetry" cf. Werner, *Loc. cit.*, pp. 29 and 129.

[2] P. 142.

[3] Cf. Sir William Ramsay, *J. Chem. Soc.*, 93, 785 (1908).

In hydrazine, using directive valences, the two nitrogen atoms should have different properties ($H_2 \rightrightarrows \underset{(\alpha)}{N} \longrightarrow \underset{(\beta)}{N} \leftleftarrows H_2$), the α atom possessing one negative charge, the β atom three negative charges. If a compound containing two molecules of hydrochloric acid and one of hydrazine is formed in which both nitrogen atoms are pentavalent, then the β nitrogen atom having gained four corpuscles and lost one is comparable to the nitrogen atom in ammonium salts and the α nitrogen atom having gained three corpuscles and lost two is comparable to the nitrogen atom in amine oxides or amine dihalides. The properties of hydrazine dihydrochloride bear out this comparison. Of the two hydrochloric acid molecules which may be added, one is given off readily, and hydrazine itself behaves more like a substance capable of forming a mono-acid base than a di-acid base. Substituting the hydrogen atoms of hydrazine by different groups, in general only one compound would be stable even if an isomer should be formed under exceptional circumstances (for instance $RHN \longrightarrow NHR'$ and $RHN \longleftarrow NHR'$). If the entering groups do not differ from each other too greatly, it would be possible to isolate such unstable isomers in some cases. This appears to have been done by Willgerodt[2] by the reaction between dinitrochlorobenzene and phenylhydrazine or α- or β-naphthylhydrazine, and perhaps in other cases.

8. Nitrogen Compounds Containing a Double Bond.

The compounds of nitrogen containing a double bond would include the azo and diazo derivatives. It will not be necessary to go into detail with the azo compounds, since so few isomers belonging to this class are known.[3]

Among the diazo compounds it will be necessary to include the diazonium compounds, which will be spoken of first. These are derived from ammonium salts in which the three hydrogen atoms are replaced by one nitrogen atom which shows similar properties. The formula of the diazonium salts may therefore be represented by

$$R \longrightarrow \underset{\substack{\downarrow \\ X}}{N} \Lleftarrow N,$$

one nitrogen being the ammonia nitrogen combined with RX, the other being the nitrous acid nitrogen. For the syn and anti diazo compounds there are evidently the two formulas containing the groupings $.\mathrm{N} \leftleftarrows \mathrm{N}.$ and $.\mathrm{N} \leftrightarrows \mathrm{N}.$ possible. In the formation of diazo compounds from a primary amine and nitrous acid, the first product formed is always the syn compound making it extremely probable that these are derived from the grouping $\mathrm{R.N} \leftleftarrows \mathrm{N.X}$ or $\mathrm{R} \longrightarrow \mathrm{N} \leftleftarrows \mathrm{N} \longrightarrow \mathrm{O} \longleftarrow \mathrm{H}$, the ammonia and nitrous acid nitrogens retaining their charges. Syn compounds can very readily be converted into anti compounds, most simply by the action of alkali in solution, but anti compounds cannot be converted directly again into syn, showing that the anti form is the more stable. This is also brought out by comparing some of the physical properties[1] of the two series. The anti diazo compounds may then be assigned the structure $\mathrm{R} \longrightarrow \mathrm{N} \rightleftarrows \mathrm{N} \longrightarrow \mathrm{O} \longleftarrow \mathrm{H}$ analogous to the stable forms of the ethylene isomers in which the two valences also act in opposite directions. The chemical reactions which show the syn compounds to be more reactive than the anti are their greater explosiveness and the fact that they can be more easily reduced and oxidized. In coupling, the syn compounds also show their great reactivity as compared with the anti.

---

[1] *Ber.*, 41, 3966 (1908).

[2] *J. prakt. Chem.*, [2] 37, 449 (1888); 43, 177 (1891).

[3] The only certain cases of isomerism here appear to be with *p*-azophenol, Willstätter and Benz, *Ber.*, 39, 3492 (1906); 40, 1578 (1907) and with azobenzene, Gortner and Gortner, THIS JOURNAL, 32, 1294 (1910).

The relation between syn diazo compounds and diazonium compounds is a very close one. They are readily transformed into each other, alkalies favoring the formation of the diazo derivatives, acids of the diazonium, while in solution both exist in equilibrium testifying to the readiness with which they are transformed into each other. All this is readily understood when directive valences are used, the structure of the two classes being represented by

$$\mathrm{R} \longrightarrow \mathrm{N} \leftleftarrows \mathrm{N} \longrightarrow \mathrm{X} \text{ and } \begin{array}{l} \mathrm{R} \longrightarrow \mathrm{N} \overset{\leftarrow}{\leftleftarrows} \mathrm{N}, \\ \phantom{\mathrm{R} \longrightarrow{}} \downarrow \\ \phantom{\mathrm{R} \longrightarrow{}} \mathrm{X} \end{array}$$

the X group or element (electronegative toward nitrogen as the direction of the valence shows) shifting its bond from the one nitrogen to the other.

The replacement of the diazo group by other groups on the benzene (or naphthalene) nucleus is a well-known and characteristic property of these compounds. The more unstable syn derivatives decompose in this way fairly readily, the ease, of course, depending to some extent upon the substance used, while with the anti derivatives these reactions do not occur, or are very slow in their progress. The greater reactivity of the syn compounds would perhaps account for this, but it seems possible in this case to look for a deeper underlying cause. The great variety of groups which combine with the benzene nucleus when the nitrogen is eliminated, including hydroxyl, alkoxyl, halogen, cyanogen, sulphur, sulphonic acid, aromatic hydrocarbon residues, etc., shows that the reaction is not limited to any one group or class. The common phenomenon in all these reactions is the elimination of nitrogen and the cause of the reaction may justly therefore be found in the tendency of the nitrogen to be set free. The difference in the nitrogen in the syn and anti diazo compounds may be represented by $\longrightarrow \mathrm{N} \substack{\longleftarrow \\ \longleftarrow} \mathrm{N} \longrightarrow$ and $\longrightarrow \mathrm{N} \substack{\longleftarrow \\ \longrightarrow} \mathrm{N} \longrightarrow$ and upon being set free, if the trivalent nitrogen still persists, the syn would be represented by $\mathrm{N} \substack{\longleftarrow \\ \longleftarrow \\ \longleftarrow} \mathrm{N}$ and the anti by $\mathrm{N} \substack{\longleftarrow \\ \longleftarrow \\ \longrightarrow} \mathrm{N}$. If the trivalent property becomes transformed into some other, then there appears to be no reason why one form should give off the nitrogen any more readily than the other. The reaction is then referred back to the tendency of the nitrogen in the diazo compounds to form the nitrogen molecule $\mathrm{N} \substack{\longleftarrow \\ \longleftarrow \\ \longleftarrow} \mathrm{N}$. This leads to the conclusion that in the nitrogen molecule, the two atoms are charged differently, one positively, the other negatively. The same fact is indicated by the formation of nitrogen when ammonium nitrite is heated, and the reverse action.[1]

---

[1] The syn compounds are more soluble and show a lower melting point than the anti.

9. Compounds Containing a Double Bond between Unlike Atoms.

So far isomerism caused by two atoms of an element combined in different ways, which was explained as being due to the difference in the direction of the valence, has been considered chiefly. The same principles should be applicable to combinations of different elements and the possibilities of isomerism due to the double bond in these cases should follow analogous rules. Following the reasoning used in the example already discussed, it is possible to limit the cases of possible isomerism somewhat in considering combinations of two dissimilar elements. When two dissimilar elements unite by a single bond, the direction in which the corpuscle is moved in order to establish this linkage is, in general, perfectly definit, the opposite direction occurring only under exceptional conditions. If a second linkage (or a double bond) is established between the two atoms, the direction in which the second corpuscle moves will either be the same or opposite to that of the first corpuscle, giving rise to two isomeric compounds of the same structure differing only in the direction of one valence. These two isomers would differ in stability, and the more stable one may for the present be assigned the structure in which both valences possess the same direction, since this appears to be the most reasonable view in the union of two dissimilar atoms. This subject may be exemplified by the carbonyl group. Following the reasoning given, the structure $:C \rightrightarrows O$ would be the stable one; if an isomer occur, the grouping $:C \rightleftarrows O$ would be assigned to it, whereas the grouping $:C \leftleftarrows O$ would be so unstable as to render the compounds in which it might be expected to exist, too unstable to be isolated. These stable isomers differ in structure then from the stable isomers in which two carbon or nitrogen atoms are united by a double bond, the direction of the two valences being opposite to each other in the latter, in the same direction in the former.

---

[1] This deduction holds only for the nitrogen molecule, but the conclusion that an atom may possess a different charge depending upon the conditions is not new. Cf. W. A. Noyes, *J. Am. Chem. Soc.*, 32, 1070. " . . . . This is in accord with the hypothesis first proposed by the writer in 1901 (*Ibid.*, 23, 463) that atoms of the same element may in different cases assume either positive or negative charges. Essentially the same fundamental idea has been proposed quite independently by Abegg and, from a wholly different point of view, by J. J. Thomson."

A large number of isomeric compounds containing a double bond between two unlike atoms are known. To begin with the simplest case of all, benzophenone is known to exist in two modifications, one stable, the other labile and going over into the stable form with great ease. Of these modifications, the stable one, melting at 48.5°, may be assigned the structure $(C_6H_5)_2C \rightrightarrows O$ and the labile one, melting at 25°, the structure $(C_6H_5)_2C \rightleftarrows O$.[1] Other ketones which exist in two modifications are known. Among these may be mentioned *p*-tolylphenylketone, stable variety melting at 59–60°, labile variety melting at 55°, and fluorenone. Perhaps the two forms of *o*-quinone and of diphenoquinone belong to this group.

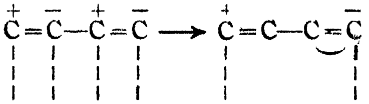
A group of substances derived from the ketones, or in general from compounds containing the carbonyl group, occur in isomeric forms which may be explained in the same way as with the simple ketones. The classes showing this isomerism are the oximes, hydrazones, semicarbazones, chloroimides, etc. It seems hardly necessary to enter into any details with regard to the structures of these classes of compounds, since the method of treatment is the same as that already used, and the stability and other relations would be taken up similarly. A few lines may, however, be devoted to the oximes. On treating an aromatic aldehyde with hydroxylamine directly the "anti" aldoxime is formed first and can be converted into the "syn" form by suitable treatment. From this, the anti form would be assigned the structure $RH : C \rightrightarrows N \longrightarrow O \longleftarrow H$ and the syn form the structure $RH : C \rightleftarrows N \longrightarrow O \longleftarrow H$. The different properties of the two forms of the aldoxime would then be due to the difference in linking between the carbon and nitrogen atoms in the two cases. Similar reasoning applies to the ketoximes, the structure to be assigned to the two forms which differ in the union between the carbon and nitrogen atoms and the reactions of these forms differing according to the influence of that union. In the Beckmann rearrangement, the group which would exchange positions with the hydroxyl depends upon the nature of that group as compared with the nature of the nitrogen atom.

[1] Schaum, *Chem.-Ztg.*, 47, 417 (1910) states that the two modifications differ chemically.

Thus the isomerism which has been explained heretofore by geometrical isomerism in all these classes may be referred to the direction of the two valences in the double bond without considering the spatial position of the groups. All double-bond isomerism may be attributed to the same cause.

10. Partial Valence.

The fundamental hypothesis used in this paper to account for chemical combination requires that the atoms joined by the transfer of a corpuscle should possess electric charges, the atom which loses the corpuscles, a positive charge, the atom which gains the corpuscle, a negative. In general, therefore, the parts of a molecule should be charged differently, and should therefore be able to attract the parts of other molecules possessing opposite charges. This attraction evidently will be different in character and intensity from the attraction between two atoms combined chemically by the transfer of a corpuscle. In this connection it is of interest to quote from Thiele's original paper on partial valence in which the analogy between double bonds and molecular magnets is drawn, in which he does not, however, refer the forces to the action of electric charges:[1] "Man könnte sich einen solchen Ausgleich vielleicht so vorstellen, dass the Atome einer Doppelbindung entgegengesetzt positiv und negativ geladen seien, $\overset{+}{C} = \overset{-}{C}$. Bei benachbarten Doppelbindungen würden sich dann the inneren Ladungen ausgleichen:



.

Man erhielte dann eine Anordrung, ähnlich der, die benutzt wurde, im mit Hülfe der 'Molekularmagnete' die Constitution der Magnete zu erklären."

Evidently with the use of directive valence, the charges on the atoms are not distributed as simply as pictured in this analogy, but each atom or group combined with the carbon atoms involved will have its effect on these. It would also not be necessary for each of the carbon atoms involved to exert its attractive force. It may be pointed out that the partial valences need not be, and probably are not, the most important factors involved in causing a chemical reaction to take place, and that all that need be assumed is that they exert a directive influence on the entering groups or atoms when addition takes place to a double bond. This fact harmonizes the conclusions drawn so far in this section with those obtained in the sections where the direction of the valences in double bonds were considered. Explanations for individual reactions on the basis of this view, which accounts for partial valence as the attraction of the electrically charged parts of a molecule will not be given here.

---

[1] *Ann.*, 306, 89–90 (1899).

Within recent years, partial valence has been used to explain a somewhat different phenomenon, namely, the formation of quinhydrones,[1] while "Nebenvalenzen" have been used to account for the existence of a number of isomeric compounds by Hantzsch.[2] With the view of partial valence, which may include the "Nebenvalenzen" as used by Hantzsch, developed here it would then appear that the electric attraction between certain atoms or groups of the same or different molecules is sufficiently strong to produce configurations stable enough to exist under ordinary conditions and to produce characteristic individual effects, such as in the first case mentioned, distinctive color. The laws governing these differences in intensity of the partial valences can only be found as a result of experimental investigation.

Electric attraction between electrically charged atoms has suggested a possible explanation for an entirely different class of phenomena, namely, that of the anomalies existing in aqueous solutions of highly ionized electrolytes. The following quotations are taken from a paper by A. A. Noyes.[3] ". . This principle is that the ionization of salts, strong acids, and bases is a phenomena primarily determined not by specific chemical affinities, but by electrical forces arising from the charges on the ions. . . . . . "

"The molecular explanation of these facts and the more general conclusions drawn from them would seem to be that primarily the ions are united somewhat loosely in virtue of their electrical attraction to form molecules, the constituents of which still retain their electric charges and therefore to a great extent, their characteristic power of producing optical effects and such other effects as are not dependent on their existence as separate aggregates. Secondly, the ions may unite in a more intimate way to form ordinary uncharged molecules, whose constituents have completely lost their identity and original characteristics. These two kinds of molecules may be designated electrical molecules and chemical molecules, respectively, in correspondence with the character of the forces which are assumed to give rise to them. . . . The facts, moreover, indicate that chemical molecules are formed from the ions in accordance with the principle of mass-action, but that electrical molecules are formed in accordance with an entirely distinct principle, whose theoretical basis is not understood."

It is evident that the two kinds of molecules referred to here are strictly comparable with the substances spoken of as formed by the transfer of corpuscles (chemical bonds) and those formed by electrical attraction or partial valence, with the addition that in aqueous solution phenomena are made apparent and predominate which do not appear to an appreciable extent with the organic compounds which were chiefly considered heretofore.

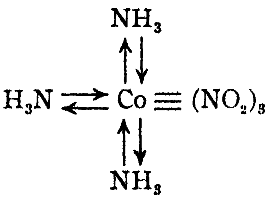
11. Complex Inorganic Salts.

The direction of the valence in the simple inorganic salts which ionize in aqueous solution can readily be determined. Some interesting conclusions have been pointed out for these in the section on Partial Valence. The complex inorganic salts cannot be treated in as simple a manner. It is not necessary, however, to develop the hypothesis for these here as this has already been done by Sir William Ramsay in his Presidential Address before the London Chemical Society in 1908.[1] The part of this address relating to the subject in question will be quoted and may serve to show how the assumptions made may be applied to the cobaltammine nitrites:.[2]

"Just as the nitrogen atom in NH_4Cl takes one electron from the hydrogen of the HCl and gives one up to the chlorine, so it appears reasonable to suppose that in these cobaltammines each nitrogen atom of the three ammonia groups takes from the cobalt atom one electron, while it gives one at the same time. The formula of the triammino-nitrite would therefore be



$$\begin{array}{ccc} & NH_3 & \\ & \uparrow\downarrow & \\ H_3N \rightleftarrows & Co & \equiv (NO_2)_3 \\ & \uparrow\downarrow & \\ & NH_3 & \end{array}$$

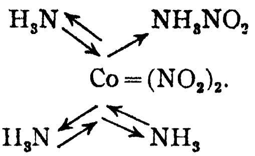
If another molecule of ammonia be added, then the cobalt atom gives to the nitrogen of the ammonia an electron, but does not receive one in return. The nitrogen atom of that ammonia group is then "overloaded" for it has received four electrons in addition to its normal five,[3] making nine in all; now it appears that no element can be associated with more than eight in all. Hence that nitrogen atom must lose an electron. This it imparts to one of the (NO_2) groups, which parts company with the cobalt atom, and, as a complex ammonium nitrite is now present, it is ionizable on solution in water. A glance at the proposed formula will explain the conception

---

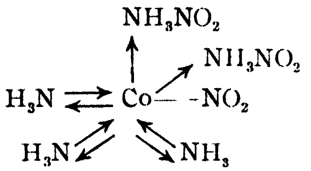
[1] "The Electron as an Element," *J. Chem. Soc.*, 93, 774.

[2] Pp. 785–7.

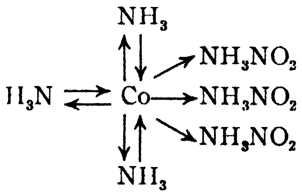
[3] The nitrogen atom is assumed by Ramsay to carry five corpuscles normally. In the deductions given here this assumption is not made in the same form, but practically the same assumption, based also upon experimental facts, is made with regard to the number of corpuscles which an atom is able to gain or lose.



The remaining formulas[1] may be written similarly, thus:



and



Why is the group $Co(NH_3)_3(NO_2)_3$ not ionizable? Let us first inquire: Why is cobalt nitrate ionizable? (Cobalt nitrite is unknown). Because the cobalt atom gives up an electron to each of the three NO_3 groups, remaining itself an ion. That is, the metal cobalt has three electrons associated with it; what we call "metallic cobalt" is a "tri-electride of cobalt." As "cobaltion," it has parted with its three electrons. But in the last of the compounds above, the cobalt has not three electrons at its disposal; it has already parted with them to the NH_3NO_2-groups. And we are led to conclude that in the non-ionizable compound the cobalt does not, as in its ordinary salts, part with three electrons, but that it receives them from the nitro groups."

This explanation of the cobaltammine nitrites evidently agrees with the views of structure developed here. The nomenclature differs slightly from that in general use. The formulation of other complex salts could doubtless be carried out in the same way, but will not be attempted here as it is only desired to show the possibilities of the conception of directive valences.

12. Summary.

An attempt has been made in this paper to apply the hypothesis of J. J. Thomson, according to which chemical bonds are formed by the transfer of a corpuscle from one atom to another, to a number of classes of compounds.[2]

The most interesting result obtained is that all cases of isomerism connected with the presence of a double bond, whether between like or unlike atoms, have been referred to the direction of the valences of the double bond, instead of to spatial configurations as heretofore.

The existence of certain isomers and the explanation of some hitherto unexplained reactions have also been referred to the directions of the valences.

---

[1] For the remaining cobaltammine nitrites.

[2] This is not the only hypothesis which may be used. The interesting deductions of J. Stark (*Jahrb. der Rad. Elekt.*, 5, 124 (1908)) based upon a different fundamental assumption may be cited, although he includes chiefly phenomena of a different kind.

The existence of "partial valence" is shown to follow from the electric charges of the atoms in a molecule.

Applications of the hypothesis to inorganic compounds have been taken from the work of A. A. Noyes and of Sir William Ramsay.

RESEARCHES ON QUINAZOLINES (TWENTY-SIXTH PAPER). THE SYNTHESIS OF SOME STILBAZOLES, HYDRAZONES AND SCHIFF BASES IN THE 4-QUINAZOLONE GROUP.[1]

BY MARSTON TAYLOR BOGERT, GEORGE DENTON BEAL AND CARL GUSTAVE AMEND.

Received September 24, 1910.

Various papers from this laboratory[2] have shown that in the 4-quinazolone group it is a relatively simple matter to prepare derivatives carrying a methyl group in position 2 and amino groups on either or both the benzene and miazine portions of the nucleus. Such substances constitute interesting material for the study of the action of these various groups with aldehydes.

For, it is well known that methyl groups on a nuclear carbon adjacent to the nitrogen of a heterocycle, as, for example, in the α-picolines, the quinaldines, and the like, easily condense with aldehydes to compounds of the type R.CH : CH.R′, in which R represents the heterocycle and R′ the radical of the aldehyde used.[3] For compounds of this type where R′ is a simple or substituted benzene nucleus, the name "stilbazole" has been introduced,[4] on account of the structural similarity of such substances to the stilbenes.

The condensation of aldehydes with *Bz*-amino compounds, or anilines, to compounds of the R.N:CH.R′, or Schiff base type, is also an old story.

Bülow[5] and others[6] have shown that aldehydes condense to hydrazones with the *N*-amino groups of nitrogen heterocycles.

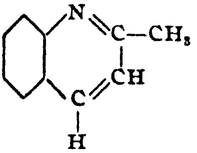
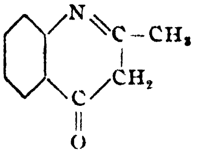
[6] Bogert and Gortner, THIS JOURNAL, 31, 947 (1909).

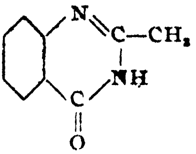
The first 4-quinazolone studied by us was the 2-methyl-4-quinazolone, whose structure resembles that of quinaldine or, still more closely, that of γ-quinaldone,



Quinaldine.

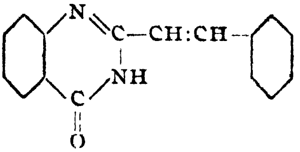


γ-Quinaldone.



2-Methyl-4-quinazolone.

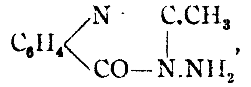
It condenses easily with aromatic aldehydes to the stilbazole; with benzaldehyde, for example, giving the simple styryl derivative,



Boiling with caustic alkali, or with strong hydrochloric acid, fails to hydrolyze these compounds to aldehyde and quinazolone again. By virtue of the $-\mathrm{CO.NH}- \rightleftarrows -\mathrm{C(OH)} : \mathrm{N} \longrightarrow$ grouping in the quinazoline portion of the molecule, they dissolve in caustic alkalies and are reprecipitated from such solutions by carbon dioxide or by weak organic acids.

2,3-Dimethyl-4-quinazolone gives the corresponding 2-styryl-3-methyl-4-quinazolone with benzaldehyde. As the condensation product in this case cannot assume the enolic condition, it is insoluble in caustic alkali solutions.

Passing on to the 2-methyl-3-amino-4-quinazolone,



$$C_6H_4\left\langle\begin{array}{l}N\cdot\ \ C.CH_3\\ \qquad\quad |\\ CO-N.NH_2\end{array}\right.,$$

the opportunity was presented for the aldehyde to condense with either the 2-methyl or the 3-amino group, giving in the one case a stilbazole (*C*-benzal), in the other a hydrazone (*N*-benzal), or, finally, with excess of aldehyde, condensation might be effected with both groups simultaneously, yielding a compound which would be both stilbazole and hydrazone in structure. As will be seen from the experiments described beyond, representatives of all three of these classes have been obtained. In connection with these experiments, the following observations are of interest:

1. With benzaldehyde and the quinazolone in equimolecular proportion, the condensation occurs first with the *N*-amino group, giving the hydrazone.

2. With excess of aldehyde, the dimolecular condensation follows, *i. e.*, aldehyde condenses with both the methyl and the amino group.

3. The hydrazone is readily hydrolyzed by boiling dilute hydrochloric acid, while the stilbazole is unaffected by this treatment. Hence, on boiling the dimolecular condensation product with 10 per cent. hydrochloric acid, the stilbazole, 2-styryl-3-amino-4-quinazolone, which could not be prepared by direct condensation, was easily obtained.

4. With cinnamic aldehyde, salicylic aldehyde, or vanillin, the aldehyde condenses only with the *N*-amino group. Heating either these hydrazones or the original 2-methyl-3-amino-4-quinazolone with excess of the aldehyde does not give the di-aldehyde condensation product, although, as has been mentioned already, these aldehydes condense freely with the 2-methyl in the absence of the 3-amino group. But, if these hydrazones be heated with benzaldehyde, then the 2-methyl is immediately changed to the styryl group. From which, it might be inferred either that this 2-methyl group is much more reactive towards benzaldehyde than towards the other aromatic aldehydes mentioned, or that if the failure of the other aldehydes to give di-aldehyde condensations is due to steric hindrance, the presence of another aldehyde group in position 3 does not prevent the entrance of the benzal group in position 2.

2-Methyl-7-amino-4-quinazolone presents a slightly different condition of affairs. Like the 2-methyl-3-amino-4-quinazolone, condensations are possible here with the methyl, the amino group, or with both. The amino group is, however, differently located in the molecule, being on the benzene and not on the miazine side of the nucleus, and in union with carbon instead of with nitrogen. Aldehydes condensing with this amino group should thus yield true Schiff bases instead of hydrazones.

In our first experiment with the 2-methyl-7-amino-4-quinazolone and benzaldehyde, a mono-benzal derivative was obtained which was apparently the Schiff base, since it could be hydrolyzed into aldehyde and quinazolone again by long boiling with dilute potassium hydroxide solution. Subsequent attempts to get this same product all failed. Irrespective of the amount of benzaldehyde used with the quinazolone, the same product resulted in all other experiments, but a product different from the one obtained in the first experiment. The fact that this product obtained in most of the experiments can be acetylated would argue the presence therein of an unchanged amino group. We do not feel satisfied with the results with this particular quinazolone, and if an opportunity presents will repeat the work. It is contrary to our experience in other cases that the 7-amino group should condense more readily with benzaldehyde than the 2-methyl, and the mono-benzal derivative isolated in the first experiment must be obtained again and further studied before we are convinced that in it the benzaldehyde has condensed with the 7-amino group.

No such complications appeared in the interaction of 2-methyl-7-

acetamino-4-quinazolone and benzaldehyde, which resulted in a smooth condensation between the aldehyde and the 2-methyl group.

In the case of 2,3-dimethyl-7-amino-4-quinazolone also, the mono-benzal condensation product obtained proved to be the styryl compound, *i. e.*, the stilbazole, from which it can be gathered that, under the conditions of our experiment at least, the 2-methyl reacts with benzaldehyde more rapidly than the 7-amino group.

Finally, in the 2 methyl-3,7-diamino-4-quinazolone, we find three groups capable of taking part in the reaction with aromatic aldehydes, yielding respectively stilbazoles, hydrazones, or Schiff bases, or compounds containing two or all of these functions simultaneously.

On heating this quinazolone with excess of benzaldehyde, all three groups reacted, the tri-benzal derivative being the chief product. At the same time there were formed two isomeric di-benzal derivatives, but in amount insufficient to identify.

When the 7-amino group was acetylated, the 2-methyl and 3-amino groups condensed smoothly with the benzaldehyde. The 6-acetamino isomer behaved similarly. When both 3- and 7-amino groups were acetylated, the 2-methyl group could be similarly condensed with the aldehyde.

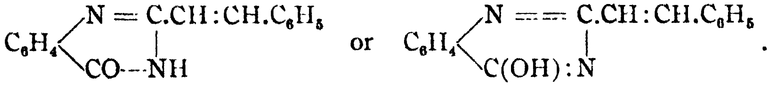
Summing up, then, our results would seem to show that, with reference to their activity towards benzaldehyde, and under the conditions of our experiments, the above groups can be arranged in the following order: first, the 3-(or *N*-) amino group; second, the 2-methyl group; and third, the 7-(or *Bz*-) amino group.

Experimental.

I. Condensations with 2-Methyl-4-quinazolone.

With the exception of the first, compounds carrying the —CO.NH— $\rightleftarrows$ —C(OH) : N— group are written in the keto form and called quinazolones.

2-Styryl-4-quinazolone (2-Styryl-4-hydroxyquinazoline),



$$C_6H_4\left\langle\begin{array}{l} N = C.CH:CH.C_6H_5 \\ \qquad\quad | \\ CO\!-\!NH \end{array}\right. \quad \text{or} \quad C_6H_4\left\langle\begin{array}{l} N == C.CH:CH.C_6H_5 \\ \qquad\qquad | \\ C(OH):N \end{array}\right. .$$

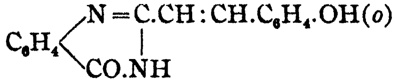
2-Methyl-4-quinazolone was mixed with slightly more than the equimolecular amount of benzaldehyde and the mixture boiled for ten minutes over the naked flame. The melt, crystallized from alcohol, yielded colorless, silky needles, melting at 252–3° (cor.).

Found: N, 11.86. Calculated for $C_{16}H_{12}ON_2$: N, 12.0.

The compound is rather difficultly soluble in alcohol, chloroform or glacial acetic acid; very difficultly soluble in ether or carbon disulphide. The benzal group is not broken off by boiling with potassium hydroxide solution or with hydrochloric acid. With bromine, in chloroform or glacial acetic acid solution, it yields a mono-bromo substitution product. No di-bromo addition was noted.[1] An effort was made to oxidize the styryl quinazolone to the 4-quinazolone-2-carboxylic acid by the method of Bamberger and Berle,[2] but the results were unsatisfactory.

In an attempt to get the intermediate alkine (*i. e.*, $C_9H_6ON_2.CH_2.CH(OH).C_6H_5$), equimolecular amounts of 2-methyl-4-quinazolone and benzaldehyde, mixed with some water, were heated in a sealed tube for 40 hours at 140°. At the close of the heating the tube was found to be filled with crystals, which when recrystallized from alcohol proved to be identical with the above 2-styryl-4-quinazolone.

2-o-Hydroxystyryl-4-quinazolone,



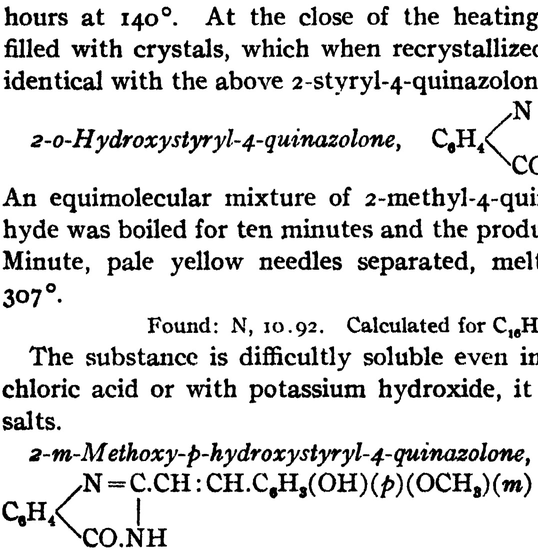
$$C_6H_4\left\langle\begin{array}{l} N = C.CH:CH.C_6H_4.OH(o) \\ \quad\;\; | \\ CO.NH \end{array}\right.$$

. — An equimolecular mixture of 2-methyl-4-quinazolone and salicylic aldehyde was boiled for ten minutes and the product crystallized from alcohol. Minute, pale yellow needles separated, melting with decomposition at 307°.

Found: N, 10.92. Calculated for $C_{16}H_{12}O_2N_2$: N, 10.60.

The substance is difficultly soluble even in hot alcohol. With hydrochloric acid or with potassium hydroxide, it yields bright canary-yellow salts.

2-m-Methoxy-p-hydroxystyryl-4-quinazolone,



$$C_6H_4\left\langle\begin{array}{l} N = C.CH:CH.C_6H_3(OH)(p)(OCH_3)(m) \\ \quad\;\; | \\ CO.NH \end{array}\right.$$

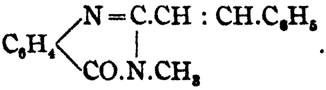
.—Equimolecular amounts of 2-methyl-4-quinazolone and vanillin were fused together over the flame until crackling ceased (ten minutes). The cold melt was crystallized repeatedly from alcohol. Pale yellow, minute needles resulted, which softened at about 275° (cor.) and at 280° (cor.) melted down to a brownish liquid.

Found: N, 9.63. Calculated for $C_{17}H_{14}O_3N_2$: N, 9.52.

The alkaline salts are a darker yellow, but possess no tinctorial power.

II. Condensation with 2,3-Dimethyl-4-quinazolone.

2-Styryl-3-methyl-4-quinazolone,



$$C_6H_4\left\langle\begin{array}{l} N = C.CH : CH.C_6H_5 \\ \quad\;\; | \\ CO.N.CH_3 \end{array}\right.$$

. — 2,3-Dimethyl-4-quinazolone and benzaldehyde were boiled together until the crackling ceased, and the cold melt was then crystallized from dilute alcohol. Fine, light yellow needles were obtained, melting at 170° (cor.).

Found: N, 10.72. Calculated for $C_{17}H_{14}ON_2$: N, 10.68.

To make certain that the 2-methyl group was the only one participating in the above reaction, some 3-methyl-4-quinazolone was heated with benzaldehyde for 6–8 hours at 180°, but no condensation ensued.

---

[1] Compare Wallach and Wusten, *Ber.*, 16, 2009 (1883); Dubke, *Ibid.*, 27, 79 (1894).

[2] *Ann.*, 273, 330.

III. Condensation with 2-Methyl-3-amino-4-quinazolone.

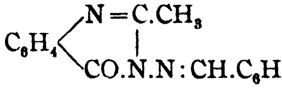
The 2-methyl-3-amino-4-quinazolone was prepared by the method of Bogert and Gortner,[1] from acetoanthranil and hydrazine hydrate.

In one case, however, another product was isolated, which we believe to be

Acetoanthranilic acetohydrazide, $CH_3CONH.C_6H_4.CONHNHCOCH_3$.—Acetoanthranil was stirred into an excess of aqueous hydrazine hydrate solution and the mixture warmed until complete solution resulted. Alcohol was then added and on dilution with water a white precipitate separated, melting at 180°, and thought at first to be impure acetoanthranilic acid (m. p. 186°). It was therefore boiled with acetic anhydride, to regenerate the acetoanthranil, but on cooling a product was obtained which crystallized from alcohol or from acetic anhydride in prisms, melting at 193° (cor.).

Found: N, 17.98. Calculated for $C_{11}H_{13}O_3N_3$: N, 17.94.

2-Methyl-3-benzalamino-4-quinazolone,



$$C_6H_4\left\langle\begin{array}{l}N=C.CH_3\\ \quad |\\ CO.N.N:CH.C_6H_5\end{array}\right.$$

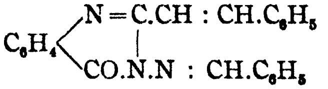
.—This has already been described by Bogert and Gortner,[2] who prepared it by boiling together for a few minutes 2-methyl-3-amino-4-quinazolone and benzaldehyde. It forms colorless prismatic needles. They give its melting point as 183° (cor.). By careful purification, we have succeeded in raising this to 187° (cor.). The condensation may be accomplished by boiling together the two constituents dry or, still better, by boiling them together in alcoholic solution.

Further heating with benzaldehyde, converts this mono-benzal derivative into the di-benzal compound described beyond.

Hydrochloride.—The powdered base was suspended in dry ether and a stream of dry hydrogen chloride passed in. When the reaction was complete, the precipitate was filtered out, washed with dry ether, and dried in vacuum over solid potassium hydroxide and concentrated sulphuric acid. It was then a nearly colorless amorphous powder, softening at 220° and decomposing without melting at about 300°.

Found: N, 14.15; Cl, 11.53. Calculated for $C_{16}H_{13}ON_3.HCl$: N, 14.01; Cl, 11.85.

2-Styryl-3-benzalamino-4-quinazolone,



$$C_6H_4\left\langle\begin{array}{l}N=C.CH:CH.C_6H_5\\ \quad |\\ CO.N.N:CH.C_6H_5\end{array}\right.$$

.—2-Methyl-3-amino-4-quinazolone and benzaldehyde were mixed, in the proportion of one molecule of the former to two of the latter, and the mixture boiled for five or ten minutes. The solution was allowed to cool somewhat and was then poured into ten volumes of hot alcohol. On cooling, yellow crystals separated, which were purified by recrystallization from alcohol and then appeared in minute, nearly colorless stellate tufts, melting at 155° (cor.).

---

[1] This Journal, 31, 947 (1909).

[2] *Loc. cit.*

Found: N, 12.04. Calculated for $C_{23}H_{17}ON_3$: N, 11.96.

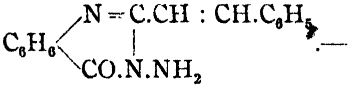
The benzal group attached to the nitrogen is easily broken out of this compound by hydrolysis with dilute mineral acid or with caustic alkali, while that attached to the CH is unaffected by such treatment. Even on boiling in simple alcoholic solution, the benzalamino group seems to suffer partial or slow hydrolytic cleavage, for the odor of benzaldehyde soon becomes quite pronounced in the recrystallization of the compound.

The same substance was obtained by heating either 2 styryl-3-amino-4-quinazolone or 2-methyl-3-benzalamino-4-quinazolone with benzaldehyde.

Hydrochloride.—Some of this was separated in the hydrolysis of the above substance with hydrochloric acid. It is a yellowish solid, not melting below 300°.

Found: N 10.52. Calculated for $C_{23}H_{17}ON_3$ HCl: N, 10.83.

2-Styryl-3-amino-4-quinazolone,



$$C_6H_6\left\langle\begin{matrix}N=C.CH:CH.C_6H_5\\ \quad|\\ CO.N.NH_2\end{matrix}\right.$$

.—2-Styryl-3-benzalamino-4-quinazolone was stirred into an excess of boiling dilute (10 per cent.) hydrochloric acid, and the benzaldehyde formed driven out with steam. The resultant clear solution was precipitated with sodium hydroxide and the yellow resinous precipitate purified by repeated crystallization from alcohol. Snowy plates, or broad needles, were thus obtained, melting at 164° (cor.).

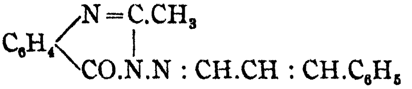
Found: N, 16.03. Calculated for $C_{16}H_{13}ON_3$: N, 15.97.

Heated with benzaldehyde, the 2-styryl-3-benzalamino-4-quinazolone is reproduced.

2-Styryl-3-benzoylamino-4-quinazolone.—The above quinazolone was suspended in water and treated with benzoyl chloride and a little caustic alkali. The crude product crystallized from alcohol in colorless needles, melting at 195° (cor.).

Found: N, 11.59. Calculated for $C_{23}H_{17}O_2N_3$: N, 11.44.

2-Methyl-3-cinnamalamino-4-quinazolone,

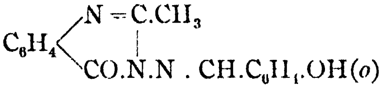


$$C_6H_4\left\langle\begin{matrix}N=C.CH_3\\ \quad|\\ CO.N.N:CH.CH:CH.C_6H_5\end{matrix}\right.$$

.—An equimolecular mixture of 2-methyl-3-amino-4-quinazolone and cinnamic aldehyde was boiled for ten minutes. The crude product was crystallized from alcohol, treated with boneblack in alcoholic solution, and finally recrystallized from dilute alcohol. It then appeared in broad, bright yellow needles, melting at 148–9° (cor.).

Found: N, 14.23. Calculated for $C_{18}H_{15}ON_3$: N, 14.53.

2-Methyl-3-salicalamino-4-quinazolone,



$$C_6H_4\left\langle\begin{array}{l} N=C.CH_3 \\ \quad | \\ CO.N.N\ .\ CH.C_6H_4.OH(o) \end{array}\right. .$$

—A mixture of 2-methyl-3-amino-4-quinazolone and salicylic aldehyde, in the proportion of one molecule of the former to two of the latter, was boiled ten minutes, the solution cooled somewhat, and poured into five times its volume of hot alcohol. On cooling, short, pale yellow needles separated, melting at 171° (cor.).

Found: N, 14.91. Calculated for $C_{16}H_{13}O_2N_3$: N, 14.53

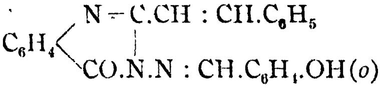
On hydrolysis with hydrochloric acid or with potassium hydroxide solution, salicylic aldehyde is split out. Long boiling with excess of salicylic aldehyde fails to introduce another aldehyde group. It does not yield an acetamino derivative with acetic anhydride.

Potassium Salt.—Bright yellow.

Hydrochloride.—The quinazolone was suspended in dry ether and dry hydrogen chloride passed in The hydrochloride is a bulky yellowish powder, melting with decomposition at about 250°.

Found N, 13.50 Calculated for $C_{16}H_{13}O_2N_3.HCl$ N, 13.31

2-Styryl-3-salicalamino-4-quinazolone,

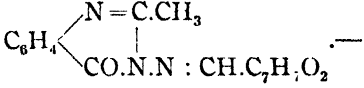


$$C_6H_4\left\langle\begin{array}{l} N=C.CH:CH.C_6H_5 \\ \quad | \\ CO.N.N:CH.C_6H_4.OH(o) \end{array}\right. .$$

—While the 2-methyl-3-salicalamino-4-quinazolone refused to condense with another molecule of salicylic aldehyde, it did condense with benzaldehyde when the two were boiled together for about ten minutes. The product crystallized from alcohol in yellowish needles, melting at 232–3° (cor.).

Found: N, 11.60. Calculated for $C_{23}H_{17}O_2N_3$: N, 11.44

2-Methyl-3-vanillalamino-4-quinazolone,



$$C_6H_4\left\langle\begin{array}{l} N=C.CH_3 \\ \quad | \\ CO.N.N:CH.C_7H_7O_2 \end{array}\right. .—$$

2-Methyl-3-amino-4-quinazolone was fused with twice the calculated amount of vanillin until water ceased to be evolved. On cooling, a pale yellow solid was obtained. This was pulverized and crystallized twice from alcohol, giving small yellowish prisms, or minute needles, melting at 215–6° (cor.).

Found: N, 13.77. Calculated for $C_{17}H_{15}O_3N_3$ N, 13.59.

With hydrochloric acid, or with potassium hydroxide, it forms deep yellow salts which show no tinctorial power.[1] Boiled with hydrochloric acid, the odor of vanillin appears.

---

[1] Compare *Ber.*, 39, 2749 (1906).

IV. Condensations with 2-Methyl-7-amino-4-quinazolone.

2-Methyl-7-amino-4-quinazolone and Benzaldehyde.—In the first experiment, the aminoquinazolone was boiled for ten minutes with excess of benzaldehyde. The clear solution on cooling deposited rosettes of needles, which on recrystallization from alcohol appeared in short, silky needles of a pale cream color, melting at 324° (cor.).

Found: N, 16.1. Calculated for $C_{16}H_{13}ON_3$: N, 15.97.

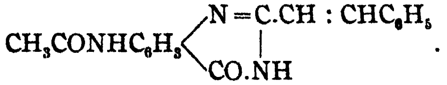
It is readily soluble in nitrobenzene, amyl alcohol or acetone; moderately soluble in boiling alcohol; difficultly soluble or insoluble in ether, chloroform, carbon tetrachloride or benzene. With concentrated hydrochloric acid, it turns a deep orange-yellow. Long boiling with dilute (10 per cent.) potassium hydroxide solution very slowly splits it into the aldehyde and quinazolone again.

Attempts to get this product a second time invariably failed. In all cases, apparently irrespective of the amount of benzaldehyde used, the product after careful purification by repeated crystallization from alcohol, melted at 324–5°. A mixture of this substance with that obtained in the first experiment showed a depression of 17° in the melting point and the analytical figures do not check either with those calculated for a mono- or a di-benzal derivative:

Found: C, 68.77 and 68.89; H, 5.38 and 4.91; N, 13.88, 13.94 and 13.72. Calculated for a mono-benzal derivative ($C_{16}H_{13}ON_3$): N, 15.97; for a di-benzal derivative ($C_{23}H_{17}ON_3$): N, 11.97.

The substance is not appreciably soluble in ether, chloroform, carbon tetrachloride or benzene. It dissolves in acetone, ethyl or amyl alcohol, or in nitrobenzene. With concentrated hydrochloric acid, it turns first yellow and then the color is discharged. With acetic anhydride, it gives an acetyl derivative which crystallizes from alcohol in colorless pearly plates, melting at 274–6° (cor.) and containing 12.57 per cent. of nitrogen.

2-Styryl-7-acetamino-4-quinazolone,



$$CH_3CONHC_6H_3\left\langle\begin{array}{l}N=C.CH:CHC_6H_5\\ \quad\;\;|\\ CO.NH\end{array}\right.$$

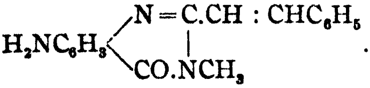
. — 2-Methyl-7-acetamino-4-quinazolone was boiled with benzaldehyde and the solid product crystallized from alcohol. Short, colorless needles, melting at 323–4° (cor.).

Found: N, 13.65 and 13.94. Calculated for $C_{18}H_{15}O_2N_3$: N, 13.77.

The compound is not appreciably soluble in water or ether, but dissolves readily in acetone, ethyl or amyl alcohol, or in nitrobenzene. Treated with concentrated hydrochloric acid, it first turns intensely yellow, then the color is largely discharged. On boiling, it dissolves slowly in the acid.

V. Condensations with 2,3-Dimethyl-7-amino-4-quinazolone.

2-Styryl-3-methyl-7-amino-4-quinazolone,



$$H_2NC_6H_3\left\langle\begin{array}{l}N=C.CH:CHC_6H_5\\ \quad|\\ CO.NCH_3\end{array}\right.$$

.—As before, the aminoquinazolone was merely boiled with benzaldehyde. On cooling, the crude product separated in yellow nodules, which were removed, washed with cold alcohol and then dissolved in hot alcohol. Water was added carefully to the hot alcoholic solution, and as the solution cooled yellow, twinned prisms crystallized out. On recrystallization, these melted at 229.5–230° (cor.). The mother liquor from these crystals showed a faint greenish fluorescence.

Found: N, 15.31. Calculated for $C_{17}H_{15}ON_3$: N, 15.16.

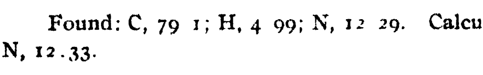
Heated with acetic anhydride, it yields the monoacetyl derivative described below.

2-Styryl-3-methyl-7-acetamino-4-quinazolone was prepared by boiling the above amino compound with acetic anhydride, as just stated, or by condensing the 2,3-dimethyl-7-acetamino-4-quinazolone with benzaldehyde. Purified by repeated crystallization from alcohol, it forms yellowish needles, melting at 272° (cor.).

Found: N, 13.32. Calculated for $C_{19}H_{17}O_2N_3$: N, 13 17.

VI. Condensations with 2-Methyl-3,7-diamino-4-quinazolone.

2-Styryl-3,7-dibenzalamino-4-quinazolone,



$$C_6H_5CH:N.C_6H_3\left\langle\begin{array}{l}N=C.CH:CH.C_6H_5\\ \quad|\\ CO.N.N:CH.C_6H_5\end{array}\right.$$

. — 2-Methyl-3,7-diamino-4-quinazolone was boiled for a few minutes with excess of benzaldehyde. Upon cooling, a yellowish granular mass was obtained. This was extracted repeatedly with boiling alcohol, and the insoluble residue dried. This insoluble product melts at 238° (cor.) and is yellow in color.

Found: C, 79 1; H, 4 99; N, 12 29. Calculated for $C_{30}H_{22}ON_4$: C, 79 3; H, 4.85; N, 12.33.

It is readily soluble in chloroform, amyl alcohol or nitrobenzene; moderately soluble in acetone or benzene; but very difficultly soluble in ethyl alcohol or ether.

On concentrating the mother liquor from the above tri-benzal compound, a substance was isolated which on repeated crystallization from alcohol appeared in short, glistening, yellowish needles, melting fairly sharply at 196° (cor.).

Found: N, 15 47. Calculated for $C_{23}H_{18}ON_4$: N, 15.3.

This corresponds, therefore, to a di-benzal derivative. Its dilute alcoholic solution shows a greenish fluorescence.

In the mother liquor from this latter was found a third substance, crystallizing in dark yellow glistening, plates, melting at 172° (cor.), and also showing a greenish fluorescence in alcoholic solution.

Found: N, 15.43 Calculated for $C_{23}H_{18}ON_4$: N, 15.3.

The results would indicate that the above two substances are isomeric di-benzal derivatives, but the amounts isolated were insufficient for further investigation.

2-Styryl-3-benzalamino-7-acetamino-4-quinazolone.—2-Methyl-3-amino-7-acetamino-4-quinazolone was boiled with excess of benzaldehyde for five or ten minutes. The quinazolone dissolved readily in the hot aldehyde and the water escaped with a strong crackling noise. On cooling, the crude product separated in clusters of dark-yellow needles. If necessary, the excess of aldehyde can be blown out by a current of steam. Recrystallized from alcohol, the product forms yellowish needles, melting at 261° (cor.).

Found. N, 13.96. Calculated for $C_{25}H_{20}O_2N_4$. N, 13.72

It is practically insoluble in water, ether, or aqueous solutions of caustic alkalies, but dissolves easily in ethyl or amyl alcohol, acetone or nitrobenzene. Its alcoholic solution shows a greenish fluorescence. With cold concentrated hydrochloric acid, it turns a deep yellow, but does not dissolve to any great extent.

2-Styryl-3,7-diacetamino-4-quinazolone was prepared in a similar manner by condensing 2-methyl-3,7-diacetamino-4-quinazolone with benzaldehyde. Purified by crystallization from dilute alcohol, it melts at 283–4° (cor.), after preliminary softening a few degrees below this point.

Found: N, 15.56 Calculated for $C_{20}H_{18}O_3N_4$: N, 15.47.

It is soluble in water, ethyl or amyl alcohol, or chloroform, when hot, or in cold acetone, and dissolves with ease in hot acetone or nitrobenzene. With cold concentrated hydrochloric acid, it turns dark yellow and dissolves. It is somewhat tribo-electric.

VII. Condensation with 2-Methyl-3-amino-6-acetamino-4-quinazolone.

2-Styryl-3-benzalamino-6-acetamino-4-quinazolone was prepared like its 7-acetamino isomer by condensing the corresponding methylaminoacetaminoquinazolone with benzaldehyde. On boiling, the benzaldehyde solution changed from light yellow to dark reddish orange. When allowed to cool, a yellow crystallin cake resulted. The excess of benzaldehyde was blown out with steam, and the residual solid crystallized from alcohol. Short, yellow, silky needles were obtained, melting at 238–9° (cor.).

Found: N, 13.88. Calculated for $C_{25}H_{20}O_2N_4$: N, 13.72.

The compound is tribo-electric. It is darker yellow than its 7-acetamino isomer, more freely soluble in alcohol, and its alcoholic solutions show a stronger fluorescence.

[CONTRIBUTION FROM THE CHEMICAL LABORATORY OF THE UNIVERSITY OF ILLINOIS]

MOLECULAR REARRANGEMENTS IN THE CAMPHOR SERIES. VI. ISOCAMPHOLACTONE.[1]

BY WILLIAM A. NOYES AND A. W. HOMBERGER.

Received October 13, 1910.

In a previous paper[2] we gave a brief report of a compound which we then considered to be a dilactone and to which we assigned the formula $C_8H_{13}O_4$. The compound is formed when isocampholactone is heated for some time with nitric acid and this led us to examine the substance qualitatively for nitrogen. For some reason, probably because the compound does not respond very readily to the usual test with metallic sodium, the result was negative, but after pursuing the study of the compound for some time further it was discovered that it has the composition of a nitrolactone,  $C_8H_{13}\begin{smallmatrix}\diagup CO \\ -O \\ \diagdown NO_2\end{smallmatrix}$. This has a molecular weight of 199 and does not agree with the determinations of the molecular weight reported in our first paper. The determinations by Victor Meyer's method were not, however, concordant and the low values found may have been due to partial decomposition.

The *isocampholactone* required for our experiment was prepared by decomposing the nitroso derivative of the anhydride of aminelauronic acid by boiling with a 10 per cent. solution of sodium hydroxide.[3] The specific rotation was determined in an 8.8 per cent. solution in alcohol, and gave $(\alpha)_D = -63.1^\circ$ at 28°. Taveau[4] gives the rotation in a 5 per cent. solution in alcohol as —60.7°.

Action of Ammonium Hydroxide on Isocampholactone.—Five tenths of a gram of isocampholactone were heated in a sealed tube in a water bath for 18 hours, till the lactone had passed into solution. The solution was evaporated in a vacuum desiccator and the residue purified by solution in absolute alcohol and precipitation with ligroin. It then melted at 137° and the analysis showed that it was the *ammonium* salt of the hydroxy acid corresponding to the lactone.

Calculated for $C_8H_{14}(OH)CO_2NH_4$: C, 57.14, H, 10.05; N 7.4.
Found: C, 57.20; H, 10.2 ; N, 7.26

---

[1] Abstract of a thesis presented by Mr. Homberger to the Graduate School of the University of Illinois in partial fulfilment of the requirement for the degree of Doctor of Philosophy.

[2] THIS JOURNAL, 31, 281.

[3] Noyes and Taveau, *Am. Chem. J.*, 32, 285; 35, 379

[4] *Am. Chem. J.*, 32, 290.

On standing in the air or on heating the salt passes back to isocampholactone.

Oxidation of Isocampholactone.—When isocampholactone is heated for 48 to 72 hours with nitric acid of sp. gr. 1.27 in a flask sealed to an upright condenser it is chiefly converted into the *nitroisocampholactone* which was described in our first paper as a lactone. If this is removed by dilution and filtration, the acid mother liquors leave on evaporation a viscous residue which crystallizes on standing.

Acid, $C_9H_{12}O_4$, melting at 138°.—After spreading the residue on porous porcelain to remove oily impurities it was crystallized from benzene. The analyses agree with the formula $C_9H_{12}O_4$.

Calculated for $C_9H_{12}O_4$ C, 58.67; H, 6.57.
Found. C, 59.09, 59.3, 59.0; H, 7.2, 7.02, 7.2.

The titration with standard alkali gave results corresponding to the molecular weights 186.0 and 186.9, for a monobasic acid. Calculated 184. The rotation of the acid in a 6 per cent. solution in alcohol was $(\alpha)_D = -42.05°$.

The Barium Salt, $(C_9H_{11}O_4)_2Ba$, was prepared by warming the acid with barium carbonate and water. It is easily soluble and separates without water of hydration.

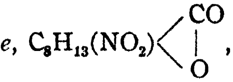
Found: Ba, 27.04. Calculated for $(C_9H_{11}O_4)_2Ba$, 27.29 per cent.

The *amide,* $C_8H_{11}O_2CONH_2$, was prepared by warming 0.5 gram of the acid with an excess of phosphorus pentachloride over a free flame in a test tube closed with a "Wallach's Aufsatz" until the mixture became liquid and pouring the cooled product into ammonium hydroxide. The amide which separated melts at 164°.

Calculated for $C_9H_{13}O_3N$: N, 7.65. Found: 7.84 per cent.

That the acid contains a lactone group was demonstrated by heating a portion of it for 12 hours on a water bath in a closed tube with somewhat more than two molecules of sodium hydroxide. Under these conditions 0.0569 gram neutralized 6.37 cc. of 0.1 *N* sodium hydroxide. Calculated for a bibasic acid, 6.18 cc.

It seems probable that this acid is formed by the oxidation of one of the methyl groups of isocampholactone.



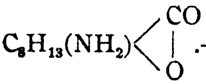
Nitroisocampholactone, $C_8H_{13}(NO_2)\left\langle\begin{matrix}CO\\ |\\ O\end{matrix}\right.$, is the principal product formed by the action of nitric acid (sp. gr. 1.27) on isocampholactone. It crystallizes from ligroin in needles. It is moderately soluble in ether and benzene. It melts at 122° and boils without apparent decomposition at 272°. The analyses were not altogether satisfactory, but leave no reasonable doubt as to the composition.[1]

---

[1] Schryver's analyses of nitrocampholactone (*J. Chem. Soc.*, 73, 562) were also unsatisfactory and somewhat similar to ours.

Calculated for $C_9H_{13}O_4N$: C, 54.29, ; H, 6.53, ; N, 7.04.
Found: C, 56 09; 55 89; H, 7.10, 7.25, N, 7 1.
54 85, 54 80; H, 7.12, 7.24; N, 7.2
54.81, 54 90, H, 7 12, 6 95.
54 90

The specific rotation of a 5.5 per cent. solution in alcohol is $(\alpha)_D$ = —85.4°.



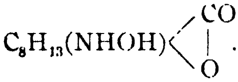
$C_8H_{13}(NH_2)\left\langle\begin{matrix}CO\\|\\O\end{matrix}\right.$

Aminoisocampholactone, $C_8H_{13}(NH_2)\left\langle\begin{matrix}CO\\|\\O\end{matrix}\right.$.—One gram of nitroisocampholactone was suspended in 4 cc. of concentrated hydrochloric acid, the mixture cooled with ice water and granulated tin, and, later, 2 or 3 cc. of hydrochloric acid added till all of the nitro compound passed into solution. Sodium hydroxide was then added in slight excess and the amino compound was extracted with ether. A large excess of sodium hydroxide seems to cause the decomposition of the product. The yield was about 0.35 gram. The aminolactone crystallizes in small, indefinit crystals, which melt at 84°.

Calculated for $C_9H_{15}O_2N$: C, 63 90; H, 8 87; N, 8.28
Found: C, 63 22; 63 10; H, 9 54; N, 8 10.

A solution of the aminolactone in absolute ether gave a precipitate of the chloride with dry hydrochloric acid. The aqueous solution of the chloride gave a yellow crystallin precipitate on standing for some time with chloroplatinic acid.

When the solution containing the amino compound was treated with a large excess of sodium hydroxide the amino compound was, apparently, decomposed and a relatively small amount of a compound melting at 152° was obtained. Owing to the small amount, this was not examined further.



$C_8H_{13}(NHOH)\left\langle\begin{matrix}CO\\|\\O\end{matrix}\right.$

Hydroxylaminoisocampholactone, $C_8H_{13}(NHOH)\left\langle\begin{matrix}CO\\|\\O\end{matrix}\right.$.—One gram of the nitroisocampholactone was dissolved in 8 cc. of glacial acetic acid and zinc dust added in small quantities, great care being taken to keep the solution cold. Zinc dust was added till the further addition caused no appreciable rise in temperature. The solution was then filtered from the excess of zinc dust and zinc acetate and the precipitate washed with a very little water. The solution was then made alkaline with sodium hydroxide, the temperature being kept low by cooling with ice. Care must be taken to avoid the use of too large an excess of sodium hydroxide. The best results were obtained by adding about 5 per cent. more than was required to neutralize the acid solution. The alkaline, turbid solution was then extracted with ether and the ethereal solution dried with sodium sulphate. The residue left on evaporating the ether was recrystallized from dry ether. It crystallizes in small, star shaped crystals, which melt at 144°.

Calculated for $C_9H_{15}NO_3$: N, 7.56. Found: N, 7.62.

Hydroxylaminoisocampholactone is slightly basic. It reduces Fehling's solution readily.

Decomposition of Nitroisocampholactone by Ammonium Hydroxide and by Sodium Hydroxide.—When nitroisocampholactone is treated with ammonium hydroxide or sodium hydroxide it is decomposed with the formation of compounds containing six atoms of carbon in the molecule. Carbon dioxide is also found but we have been unable to discover what becomes of the other two carbon atoms or to interpret the action which takes place.

Formation of the Amide, $C_5H_8NO_2CONH_2$.—This amide is formed when nitroisocampholactone is warmed with alcoholic ammonia or when it is allowed to stand, with frequent shaking, with cold concentrated aqueous ammonium hydroxide. The product was obtained by evaporation at ordinary temperatures in a strong current of air. The residue was recrystallized from benzene with the addition of a little petroleum ether. It melts at 96–97°.

Calculated for $C_6H_{10}O_3N_2$: C, 45.57, H, 6.3 ; N, 17.71.
Found: C, 45.7, 45.6; H, 7.0, 7.06; N, 17.6, 17.6
45.8, ; N, 7.14 ; N, 16.6.

Saponification of the Amide.—One-tenth of a gram of the amide was heated for 12 hours with 10 cc. of 0.5 *N* sodium hydroxide. The solution was then acidified and extracted with ether and the residue from the ethereal solution converted into the barium salt by warming with barium carbonate and water. Two samples of the salt prepared in this way lost on drying, 9.62 and 9.83 per cent. water. Calculated for $(C_6H_8NO_4)_2Ba$ $2^1/_2$ H_2O, 9.03 per cent. The anhydrous salt gave 30.34 and 30.40 per cent. Ba. Calculated 30.30 per cent. The acid recovered from the barium salt melted at 73° and was identical with the acid formed by the decomposition of nitroisocampholactone with sodium or barium hydroxide.

Acid, $C_5H_8O_2N.CO_2H$.—One gram of nitroisocampholactone was put in a test tube with 30 cc. of 0.5 *N* sodium hydroxide and allowed to stand with occasional shaking till all had dissolved. The solution was acidified with hydrochloric acid and extracted with ether. The ethereal solution was dried with sodium sulphate and the ether distilled. From the residue the barium salt of the acid was prepared by treatment with water and barium carbonate. After filtering from the excess of carbonate the solution was concentrated in a vacuum desiccator. The barium salt crystallizes well in needles which are moderately soluble in water. From the pure barium salt the acid was recovered by acidifying its solution with hydrochloric acid and extracting with ether. The acid is easily soluble in ether and in benzene, almost insoluble in ligroin. It melts at 73–74°. The acid appears to decompose and become semisolid on standing. Perhaps for this reason the analyses, especially the nitrogen determinations are not very satisfactory, but when these are taken with the titration values and the composition of the barium salt the formula assigned to the acid seems to be established.

Calculated for $C_8H_9O_4N$ C, 45.2 , H, 5.66 ; N, 8.80.
Found: C, 45.6, 45.8, 45.8, H, 5.9, 6.35, 6.4; N, 7.8, 7.5

Titration with 0.1 *N* sodium hydroxide gave a molecular weight of 162.9 and 163.0; with barium hydroxide 166. Theory 159

The Barium Salt, $(C_6H_8NO_4)_3Ba. 2\frac{1}{2} H_2O$ was analyzed completely because of the apparent instability of the acid. For the carbon determinations it was mixed with potassium dichromate to expel the carbon dioxide from the barium carbonate.

Calculated for $(C_8H_9NO_4)_2Ba.2\ 1/2\ H_2O$: C, 28.9 ; H, 4.2
Found: C, 29.2, 29.0; H, 4.8, 44.7.

The anhydrous salt gave 6.38 per cent. N, calculated 6.14

The salt lost 9.73 per cent water at 80°. Calculated for 2 1/2 H_2O, 9.04 per cent. The anhydrous salt gave 30.34 and 30.27 per cent Ba; calculated 30.30

From lack of time and the difficulty of preparing the material we have been unable to undertake experiments which might throw light on the structure of the acid.

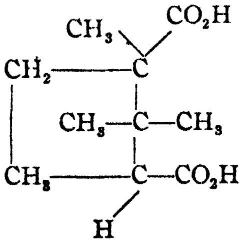
MOLECULAR REARRANGEMENTS IN THE CAMPHOR SERIES. VII. DERIVATIVES OF ISOCAMPHORIC ACID; *l*-DIHYDROHYDROXYCAMPHOLYTIC ACID.

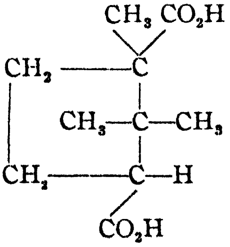
BY WILLIAM A NOYES AND LUTHER KNIGHT.

Received October 13, 1910.

It is generally assumed that *d*-camphoric acid and *l*-isocamphoric acid, which, as Aschan has shown, are each convertible into the other, are stereomers and differ only in that one is a *cis* and the other a *trans* form. This may be expressed by the following formulas:



d-Camphoric acid.



l-Isocamphoric acid.

Since methyl groups are known to shift from one carbon atom to another at much lower temperatures and under the influence of much less vigorous agents than those used to convert camphoric to isocamphoric acid the evidence for the structure of the latter does not appear to be altogether conclusive and it seemed to be of interest to obtain further evidence on this point. The study of the subject is far from complete but we have already obtained interesting and unexpected results.

Preparation of Isocamphoric Acid.—The method of preparing *l*-isocamphoric acid by heating *d*-camphoric acid with a mixture of hydrochloric and acetic acids[1] has been modified by largely increasing the proportion of camphoric acid used and also decreasing the amount of hydrochloric acid. The tubes are charged with 50 grams of *d*-camphoric acid, 25 cc. of glacial acetic acid and 2 cc. of concentrated hydrochloric acid (1.19). After sealing, the tubes are heated for ten hours at 170–180°. On account of the larger amount of acetic acid used the contents of the tubes are liquid after cooling. The acetic and hydrochloric acids are completely expelled by evaporation on the water bath and the residue after powdering finely is allowed to stand for an hour or longer with one-fourth of its weight of acetyl chloride (instead of the very large excess used by Aschan). The mixture is then treated with water and acid sodium carbonate, which dissolves the isocamphoric acid leaving the *d*-camphoric anhydride dissolved. From the filtrate the *l*-isocamphoric acid is precipitated by hydrochloric acid. In this manner 100 grams of the *d*-camphoric acid gave 37 grams of an acid containing 95.5 per cent. of isocamphoric acid as shown by the rotation. The camphoric anhydride which is recovered may be used for treatment with acetic and hydrochloric acids again, after crystallizing it from alcohol, and in this manner the conversion to isocamphoric acid may finally be made almost quantitative. The isocamphoric acid is easily purified by crystallization, best by dissolving it in a small amount of strong alcohol, adding 3 or 4 volumes of hot water, and allowing the solution to cool while exposed to the air, allowing a part of the alcohol to evaporate. The purified acid gave in a 10 per cent. alcoholic solution a rotation of $(\alpha)_D = -47.1°$, Aschan gives $-47.1°$.

α-Monomethyl Ester of l-Isocamphoric Acid.[2]—As with *d*-camphoric acid and its derivatives the secondary carboxyl of *l*-isocamphoric acid is much more easily esterified than the tertiary.[3] It is, accordingly easy to select conditions which will give chiefly the α-acid ester.

[1] Aschan, *Ber*, 27, 2005.

[2] Assuming that isocamphoric acid is stereomeric with camphoric acid, the secondary carboxyl is called α and the tertiary carboxyl β. See Noyes, *Am. Chem. J.*, 16, 500; 18, 686.

[3] Noyes, *Am. Chem. J.*, 18, 686.

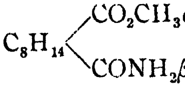
One hundred grams of isocamphoric acid, 400 cc. of methyl alcohol and 40 cc. of concentrated sulphuric acid were boiled for 20 minutes with a return condenser. The methyl alcohol was then distilled away under diminished pressure and the mixed esters which were precipitated with water were shaken with a strong solution of sodium carbonate which dissolved the acid ester. The neutral ester, which is always formed and which may become the principal product if the boiling is too long continued, was taken up with ether and distilled under diminished pressure. The acid ester was precipitated on adding hydrochloric acid to the sodium carbonate solution. The yield of acid ester may reach 95 per cent. of the theory.

The Dimethyl Ester of Isocamphoric Acid, $C_2H_{14}(CO_2CH_3)_2$, boils at 146° under 27 mm. pressure and has a specific gravity of 1.073 at 20° and 1.069 at 25°. Its specific rotation, $(\alpha)_D^{21°} = —65.2°$. In 10 per cent. alcoholic solution $(\alpha)_D = —63.6°$.

The α-Monomethyl Isocamphoric Ester prepared as described above was crystallized from petroleum ether. It crystallizes in needles which melt at 88°. In 10 per cent. alcoholic solution $(\alpha)_D = —57.9°$.

0.2340 g required for neutralization 10.85 cc. and 0.4640 g required 21.66 cc. 0.1 *N* KOH, calculated, 10.92 and 21.69 cc.

Amide of the α-Monomethyl Ester of Isocamphoric Acid,

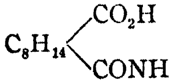


$C_8H_{14}\begin{cases}CO_2CH_3\alpha\\CONH_2\beta\end{cases}$.

—The acid methyl ester last described was mixed in a distilling bulb with an equal weight of phosphorus pentachloride, the mixture being cooled when more than a few grams are used. When the reaction is complete the phosphorus oxychloride is distilled away as rapidly and under as low a pressure as possible. The acid chloride is then poured carefully into a slight excess of ammonia (0.90), the latter being thoroughly cooled with ice or a freezing mixture. The amide obtained was crystallized from dilute alcohol. It crystallizes in plates on spontaneous evaporation of the alcohol. It melts at 157°. In 10 per cent. alcoholic solution $(\alpha)_D = —60.05°$.

The analysis gave 6.68 per cent. N; calculated, 6.57 per cent.

β-Isocamphoramidic Acid,



$C_8H_{14}\begin{cases}CO_2H\\CONH_2\end{cases}$

.—The amide of the monomethyl ester of isocamphoric acid was dissolved in alcohol, 10 per cent. in excess of one molecule of sodium hydroxide in a 30 per cent. solution was added and the mixture was heated for an hour or two on the water bath. Under these conditions the methyl ester is completely saponified while the amide group is scarcely affected. After removal of the alcohol by evaporation the β-isocamphoramidic acid was precipitated by hydrochloric acid and crystallized from dilute alcohol. It crystallizes in needles which melt at 165–166°.

The analyses gave 7.07 and 7.11 per cent. N; calculated 7.03 per cent. 0 0485 g took 2.3 cc. 0.1 N NaOH; calculated, 2 35 cc.

Isodihydroaminocampholytic Acid,  $C_8H_{14}\left<\begin{matrix}CO_2H\\NH_2\end{matrix}\right.$, was prepared from the isocamphoramidic by treating a solution of its sodium salt with a solution of sodium hypobromite.[1] The latter solution was prepared by aspirating the vapor of the measured or weighed amount of bromine through a 10 per cent. solution of sodium hydroxide.[2]

The Hydrochloride, $C_8H_{14}CO_2HNH_2.HCl$, was obtained by evaporating the acid solution to dryness and extracting the residue with strong alcohol. It is very easily soluble and crystallizes from concentrated solutions in needles. These do not melt at 250°.

0.0957 g. required 4.4 cc. 0.1 N $AgNO_3$; calculated, 4.5 cc.

The Lead Salt, $(C_8H_{14}NH_2CO_2)_2Pb$ was prepared by precipitation from an acetic acid solution and purified by washing with hot water in which it is almost insoluble.

The analysis gave 38.8 and 37.4 per cent. Pb; calculated, 37.8 per cent

The Free Isodihydroaminocampholytic Acid (not very pure) melts at 225–227°. When heated to 250 or 300° it gives an anhydride and the latter gives a nitroso compound which melted at 194° when freshly prepared but at 174–175° after standing overnight. These will be studied further.

When a solution of the hydrochloride of isodihydroaminocampholytic acid is treated with the calculated amount of a 20 per cent. solution of sodium nitrite introduced with a pipet beneath the former so that the two solutions mix by diffusion there are formed, apparently, a hydrocarbon, a lactone, *d*-campholytic acid and *l*-dihydrohydroxycampholytic acid. Only the last has been obtained in a fairly pure condition and fully identified.

The products at first obtained were taken up with ether and after removal of the latter the hydrocarbon, lactone and campholytic acid were distilled with steam. The lactone and campholytic acid were separated by means of sodium carbonate. The rotation of the campholytic acid finally obtained was +46° and it gives by titration results agreeing closely with the theory, but, in consideration of the small amount thus far obtained and of the fact that the rotation is not, as it should be, the same, though of sign opposit to that of *l*-campholytic acid[3] there is still some slight doubt as to the nature of the compound.

---

[1] Noyes, *Am. Chem. J.*, 16, 503.

[2] Dehn, THIS JOURNAL, 31, 526, footnote.

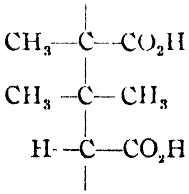
[3] Noyes and Phillips found —59.6° at 18°. *Am. Chem. J.*, 24, 291.

The l-Dihydrohydroxycampholytic Acid, $C_8H_{14}{<}^{CO_2H}_{OH}$, which remained behind after distillation of the other products with water vapor crystallized from water in granular crystals which melted at 132°. When these crystals were mixed with *d*-dihydrohydroxycampholytic acid, which melts at the same temperature, the melting point rose to about 170°, approaching that of the racemic acid.[1] The rotation in an aqueous solution containing 1.45 per cent. of the acid was $(\alpha)_D = -70.04°$. Noyes and Phillips[2] give +71.5 for the dextro acid.

0.1389 g. required 8.0 cc of 0.1 *N* NaOH, calculated, 8.07 cc

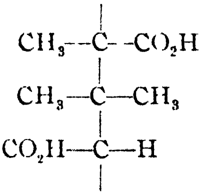
These results establish the identity of the acid as the levo form of dihydrohydroxycampholytic acid. The formation of this acid was wholly unexpected. If we represent the configuration of that part of the camphoric acid molecule containing the two asymmetric carbon atoms in the usual manner the results obtained establish the following relations as most probable:

d-Camphoric acid



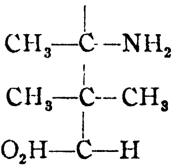
$$\begin{array}{c} | \\ CH_3-C-CO_2H \\ | \\ CH_3-C-CH_3 \\ | \\ H-C-CO_2H \\ | \end{array}$$

l-Isocamphoric acid.



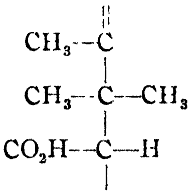
$$\begin{array}{c} | \\ CH_3-C-CO_2H \\ | \\ CH_3-C-CH_3 \\ | \\ CO_2H-C-H \\ | \end{array}$$

Isodihydroaminocampholytic acid.



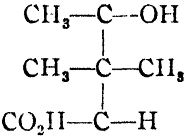
$$\begin{array}{c} | \\ CH_3-C-NH_2 \\ | \\ CH_3-C-CH_3 \\ | \\ CO_2H-C-H \end{array}$$

d-Campholytic acid.



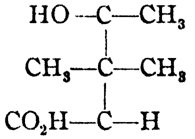
$$\begin{array}{c} \| \\ CH_3-C \\ | \\ CH_3-C-CH_3 \\ | \\ CO_2H-C-H \\ | \end{array}$$

Isodihydrohydroxycampholytic acid



$$\begin{array}{c} CH_3-C-OH \\ | \\ CH_3-C-CH_3 \\ | \\ CO_2H-C-H \end{array}$$

l Dihydrohydroxycampholytic acid.



$$\begin{array}{c} HO-C-CH_3 \\ | \\ CH_3-C-CH_3 \\ | \\ CO_2H-C-H \end{array}$$

The formation of *d*-campholytic is entirely in accord with the theory, since in this acid one of the asymmetric carbon atoms of the isocamphoric acid has lost its asymmetry through the formation of the double union. The formation of *l*-dihydrohydroxycampholytic acid is not so easily explained. From its method of formation we should expect for this the configuration of an isodihydrohydroxycampholytic acid which is not the optical antipode of *d*-dihydrohydroxycampholytic acid, but which has the methyl and hydroxyl groups reversed. This recalls the fact that *l*-campholytic acid adds hydrobromic acid to form *d*-bromodihydrocampholytic acid,[1] taking up the hydrobromic acid asymmetrically. The *d*-campholytic acid would, of course, give *l*-dihydrohydroxycampholytic acid in a similar manner. It is probable from this that the left form of the hydroxy acid is more stable than the expected isodihydrohydroxycampholytic acid and that a portion of the latter is transformed to the former by the action of the nitrous acid—or it may be that *d*-campholytic acid is formed as an intermediate product and that this adds water to form the *l*-dihydrohydroxycampholytic acid.

SOME ACID CONSTITUENTS OF SOIL HUMUS.[2]

BY OSWALD SCHREINER AND EDMUND C. SHOREY.

Received September 27, 1910

The complex character of the humus or organic matter of the soil need hardly be emphasized here, nor need the complexity of the so-called humic acid be again mentioned other than to remark that so many organic compounds, neutral, basic and acid, have been isolated therefrom in these researches that its claim to chemical unity is absolutely refuted and its non-existence proved. The present paper is a further contribution to the definit knowledge of the chemical nature of this organic soil complex and gives a description of several acids isolated therefrom. The isolation of other acid substances from soils, picolinecarboxylic acid, dihydroxystearic acid and agroceric acid, are reported in earlier papers.[3]

α-Monohydroxystearic Acid, $C_{18}H_{36}O_3$.—When the humus extract of a soil obtained by extraction with dilute alkali is acidified, a brown, flocculent precipitate of the so-called humus substances is formed. If this precipitate is separated by filtration, washed and treated while still moist with boiling 95 per cent. alcohol, a portion of the precipitate goes into solution. The amount of the humus precipitate so dissolved varies with the character of the soil treated, but the alcoholic solution obtained in this way is always dark-colored. On careful evaporation of this alcoholic solution, adding water to keep the volume constant until the alcohol is removed, there is formed a brown or reddish brown precipitate which can be separated by filtration. When so separated, washed and dried, it is in the form of resinous lumps or powder, varying in color, melting point and composition, with the soil from which it was obtained.

On extracting this resinous material with petroleum ether there is obtained an extract generally colorless or light-colored, which on evaporation of the petroleum ether leaves a residue which may vary from an oily, semi-solid mass to a waxy solid. This residue is generally wholly soluble in hot alcohol. From this alcoholic solution there sometimes separates on cooling a white or yellowish microcrystallin mass or powder which in the case of one soil has been identified as α-hydroxystearic acid.

---

[1] Noyes and Phillips, *Am. Chem. J.*, 24, 24, 291.

[2] Published by permission of the Secretary of Agriculture.

[3] THIS JOURNAL, 30, 1295, 1599 (1908); Bureau of Soils, U. S. Dept. Agr. *Bull.* 53, (1909).

The soil from which this compound was obtained was a sample of Elkton silt loam, a type covering a considerable area in Maryland. This soil is almost white in color, high in clay and silt and contains 0.53 per cent. organic carbon and 0.066 per cent. nitrogen. The sample examined was one of several hundred pounds obtained from the eastern shore of Maryland.

This soil when treated with 2 per cent. sodium hydroxide solution yields an extract much darker than might be expected from a soil so light in color. From this brown alkaline extract there is precipitated on acidifying with sulphuric acid a brown, flocculent mass. On separation of this by filtration, washing and treating with boiling 95 per cent. alcohol, there is obtained an alcoholic solution nearly as dark in color as the original alkaline extract. The precipitate formed by evaporation of the alcohol and addition of water was, after filtration, washing and drying, a brown mass easily pulverized.

Extraction of this brown powder with petroleum ether and evaporation of the solvent left an oily, semi-solid, light-yellow mass, which was completely soluble in hot 95 per cent. alcohol. On cooling, this alcoholic solution there separates a yellow, microcrystallin powder, which after separation by filtration, washing with cold alcohol, dissolving again in hot alcohol, and repeating the separation several times, can be obtained free of color and of constant melting point.

The substance so obtained melts at 84-85°, is soluble with difficulty in cold alcohol, readily in hot alcohol, cold ether or petroleum ether. It crystallizes usually in small irregular leaflets, but can be crystallized from alcohol by very slow cooling, in six-sided plates. It forms salts with alkalies soluble in water and can be obtained from such solution unchanged by acidifying and extracting with ether.

The analysis of this compound gave the following:

Calculated for $C_{18}H_{36}O_3$: C, 72.00; H, 12.00
Found: C, 72.09; H, 12.17

This composition corresponds with that of the monohydroxystearic acids, two of which are known, designated α and β, respectively, and having the formula $C_{18}H_{36}O_3$. The properties of the acid isolated from the soil fix it as the α acid. The α acid is much less soluble in alcohol than the β acid and the β acid, moreover, forms an anhydride on heating with strong hydrochloric acid, which is not the case with the α acid nor the acid from the soil. The melting points of the α and β acids are so nearly the same that this property cannot be used to distinguish between them. The melting point of the pure α acid artificially prepared remained unchanged on mixing with the acid from the soil. This fact, together with the composition found and sparing solubility in alcohol and failure to form an anhydride, is sufficient to establish the identity of the acid from the soil as α-monohydroxystearic acid.

α-Hydroxystearic acid is easily made in the manner described by Sadomsky.[1] When stearic acid is treated with red phosphorus and bromine, α-bromostearic acid is formed. On heating this with alcoholic potash the potassium salt of α-hydroxystearic acid is formed and on acidifying the aqueous solution of this salt the acid is set free and can be extracted with ether.

α-Hydroxystearic acid is not known to occur in any natural animal or vegetable product and up to the present has been isolated from only one soil.

Two hydroxy acids of the fatty series have been isolated from soils, but neither are known as natural products. These are α-hydroxystearic acid and the dihydroxystearic acid previously described.[2] Both must be looked on at present as the products of the action of microorganisms, probably fungi, on some of the organic matter known to be of plant or animal origin.

While at present little is known of the processes by which these compounds are formed in the soil and little can be said that is not of a speculative nature, it may be of interest at this point to note the laboratory methods by which hydroxy acids are formed. Three general methods are known by which the hydroxy acids are formed from the corresponding acid. These are: Making a halogen substitution product and treating this with silver oxide and water; making an amino derivative and treating this with nitrous acid; and making a sulphonic acid derivative and treating it with caustic potash.

In attempting to find a parallel between these reactions and the processes likely to take place in the soil, the second method seems to be the only one that offers any foundation for a theory. It is known that amino compounds result from the decomposition of more complex nitrogenous compounds and may possibly be formed or built up by the action of ammonia, which is commonly formed in soils. Nitrous acid, as the result of denitrification or as the first stage in the change of ammonia into nitrates, is formed in nearly all soils and would supply the reagent required in the second stage of the reaction.

In addition to these purely chemical methods of formation, there are to be considered the biological formations by fungi or bacteria, but this would lead somewhat afield from the purposes of the present article.

---

[1] *Ber.*, 24, 2388 (1891).

[2] Bureau of Soils, U. S. Dept. Agr., *Bull.* 53, (1909). THIS JOURNAL, 30, 1599 (1908).

While α-hydroxystearic acid is not known as a natural product, it must be remembered that natural fats and oils are usually complex mixtures of glycerides and that the chemistry of such glycerides as occur in these products in small amounts is very incomplete. More complete chemical knowledge of the natural fats and oils may show the presence of α-monohydroxystearic acid. The method of its laboratory preparation does not suggest any possible parallelism in the soil as was the case when the origin of dihydroxystearic acid was under discussion.

In the earlier literature of the hydroxystearic acids there is some confusion of nomenclature, as well as disagreement regarding their constitution. The β acid described by Saytzeff[1] was designated as the α acid by Geitel.[2] The designations α and β acid seem to have been primarily used to distinguish isomers, the constitutions of which were not known. The constitution, as now accepted and established by Shukov and Shestakov[3] is not in harmony with the common meaning of α and β designations. In the simple hydroxy fatty acids the term α is applied to that acid having the hydroxyl group next the carboxyl group; for example, α-hydroxypropionic acid (lactic) is represented thus: $CH_3.CHOH.COOH$; the term β is applied to that acid having the hydroxyl on the second carbon atom; for example, β-hydroxypropionic acid (hydracrylic) is represented thus: $CH_2OH.CH_2COOH$. The constitution of the α and β-hydroxystearic acids is represented as follows: α acid, $CH_3(CH_2)_6CH.OH(CH_2)_9COOH$; β acid, $CH_3(CH_2)_7CH.OH(CH_2)_8COOH$. In neither case is there α or β structure. The authors in discussing these formulas used the designations: 1.11 for the α acid, and 1.10 for the β acid, 1 being the carbon atom of the carboxyl group and 10 and 11 the carbon atoms counting from 1 to which the hydroxyl group was attached. Since, however, these acids are still generally described and referred to in the literature as α and β, these terms have been used in this paper with this explanation.

Paraffinic Acid, $C_{24}H_{48}O_2$.—The cold alcoholic solution from which α-hydroxystearic acid has separated in the manner just described is yellow in color and evaporation of the alcohol leaves a semi-solid, oily mass. On standing some time crystals form in this mass, but the nature of the material was such that they could not be separated without great loss and so this was not attempted. The oily mass was dissolved again in alcohol and an alcoholic solution of lead acetate added. This gave a yellow precipitate which was separated by filtration, washed with alcohol, suspended in alcohol and treated with hydrogen sulphide. After separation from the lead sulphide the alcoholic solution was allowed to evaporate slowly, leaving a somewhat waxy mass of leaflets. This mass was purified by dissolving again in alcohol and repeating the operation of precipitation with lead acetate and finally drying on a porous plate. The body so obtained was light yellow in color and melted at 45-48°. Analysis gave the following figures:

[3] *Ibid.* (2), 67, 414 (1903).

Calculated for $C_{24}H_{48}O_2$: C, 78.20; H, 13.00.
Found: C, 78.40; H, 13.29.

This composition, the melting point and physical properties correspond with paraffinic acid, $C_{24}H_{48}O_2$, described by Pouchet[1] as obtained by the action of fuming nitric acid on paraffin.

The research of Pouchet on which alone the existence of paraffinic acid rests is, as published, inconclusive as to its being a definit chemical compound. The quantity of this substance obtained from the soil was insufficient for any extended research and so far the character of the compound obtained from paraffin has not been studied except that the following facts were established. Paraffin was treated with fuming nitric acid in the manner described by Pouchet and a compound obtained having the properties and composition stated by him. Elementary analysis of this substance gave the following figures:

Calculated for $C_{24}H_{48}O_2$: C, 78 2; H, 13 0.
Found C, 78 1; H, 13 3.

The properties and composition of this compound corresponded with those of the substance obtained from the soil and there is little doubt that whatever may be the nature of the two substances, they are identical. With this understanding, the name paraffinic acid is applied to the soil compound. This body has so far been obtained from but one soil, the Elkton silt loam already described. A number of soils have been examined that gave at the point where paraffinic acid was obtained in the case of the Elkton silt loam a precipitate with alcoholic lead acetate, but the quantity of material has been either too small for identification or has had other properties and composition.

Very little can be said regarding the possible origin of paraffinic acid in the soil. Several solid hydrocarbons of the paraffin series have been shown to occur in plants and may therefore be a part of the organic matter added to the soil. Oxidation of these in the soil might give rise to the substance found.

It may be noted in this connection that it is well established that paraffin can be oxidized in the laboratory, but usually by rather vigorous treatment. Gill and Mensel[2] found that on treating paraffin with dilute nitric acid or chromic acid it was oxidized to cerotic acid, $C_{27}H_{54}O_2$, acetic acid and succinic acid. Pouchet in the research referred to found succinic acid in addition to paraffinic acid, but no cerotic acid.

---

[2] *Zeit. Chem.*, 1869, 65.

Lignoceric Acid, $C_{24}H_{48}O_2$.—When a soil high in organic matter is carefully heated in a closed tube, there is obtained a dark-colored, tarry distillate, which in some cases sets on cooling to a semi-solid, crystallin mass.

A peat soil containing 27 per cent. of organic carbon treated in this way gave a distillate of this character in considerable quantity. The semi-solid mass on washing with cold alcohol was freed from much of its color with little loss of solid matter. The material so washed was completely soluble in hot alcohol from which it separated on cooling in microcrystallin form. On repeating this solution and separation several times the material was obtained nearly free of color. Treatment at this stage with cold petroleum ether removed the remaining color and a small quantity of oily matter. The body after this purification melted at 80–81°, was soluble in ether and hot alcohol, little soluble in cold alcohol and insoluble in water. Its elementary composition was found to correspond to the formula, $C_{24}H_{48}O_2$.

Calculated for $C_{24}H_{48}O_2$	C, 78 2; H, 13 0
Found	C, 78 1; H, 13 2

The compound dissolved in aqueous alkalies and was set free from such solution unchanged on addition of a mineral acid. The properties, melting point and composition indicate the identity of this compound as lignoceric acid first described and obtained by Hell and Hermanns[1] from the solid residue or "paraffin" of beechwood tar. It is also found[2] as a glyceride in peanut oil.

It is generally assumed that the lignoceric acid found in wood tar is the result of decomposition effected by the method of treatment and that it does not occur as such in the wood. In the case of the soil, however, certain observations indicated that this might not be the case. It was observed that if the soil was heated to a high temperature or the heating done rapidly the yield of solid matter in the distillate was very small. When the heating was done carefully and the temperature raised only to the point where a distillate could be obtained, the solid product seemed to be the result of distillation directly from the soil and when the operation was carried on in a glass tube such distillation could actually be observed, the melted distillate collecting on the upper, cooler side of the tube and being driven forward as heat was applied, just as water would be. It was also found that the purified lignoceric acid obtained from the soil in the manner described could by careful heating be distilled with little or no decomposition.

---

[1] *Ber.*, **13**, 1713 (1880).

[2] Kreiling, *Ber.*, **21**, 880 (1888).

With the object of extracting the lignoceric acid from the soil if it existed as such, the soil was treated with boiling 95 per cent. alcohol, the extract filtered hot and allowed to cool. On cooling, a voluminous precipitate separated from the dark-colored extract. This was separated by filtration and purified by dissolving several times in hot alcohol from which it separated on cooling and finally by washing with cold petroleum ether. The compound so obtained corresponded in all properties with that obtained by distillation. It melted at 80-81° and elementary analysis gave the following figures:

Calculated for $C_{24}H_{48}O_2$: C, 78.2; H, 13.0.
Found: C, 78.2; H, 13.8.

The identity of the two compounds obtained from the soil by distillation and by extraction with hot alcohol is thus established. It follows that lignoceric acid exists in the soil as such.

Regarding the source of the lignoceric acid in the soil there are two possibilities suggested by our knowledge of the compound. It is, as has been already stated, present in peanut oil as a glyceride and may be a component of other vegetable oils and be somewhat widely distributed in plants in small amounts, in which case it might occur in the soil as a residue of the decomposition of such glycerides.

Lignoceric acid is obtained by the distillation of wood, presumably through the decomposition of woody tissue. It is possible that similar decomposition through the agency of microorganisms may take place in the soil.

PENTOSANS IN SOILS.[1]

BY EDMUND C SHOREY AND ELBERT C. LATHROP.

Received September 28, 1910.

Carbohydrates, represented by sugars, starch and compound celluloses, make up by far the greater portion of the organic substance of plants and so form the greater portion out of which soil organic matter is made. The extreme susceptibility of these substances to fermentation or decomposition by microörganisms renders them, probably, the most unstable organic material added to soils. Sugars and starch are used by a great variety of bacteria and fungi as food and no doubt disappear as such long before the cell tissues break up and become part of the soil. The cell wall and fibrovascular tissues are made up for the most part of a complex compound containing a carbohydrate or cellulose radical. These resist the action of microörganisms longer and in the breaking up of the tissues due to the decay of the least resistant portions, this complex probably gets into the soil to some extent unchanged.

---

[1] Published by permission of the Secretary of Agriculture.

The products of decomposition of such carbohydrates as starch and sugars, are fairly well known and are for the most part simple compounds, such as alcohol, acetic acid and carbon dioxide. The more resistant complexes, the so-called compound celluloses, contain other groups in addition to the carbohydrate radical and can give rise in decay to a great variety of products some of them still quite complex, but resistant to further action of bacteria or fungi. Because of this complexity of the material itself and of its decomposition products, the character of the changes which take place in the decay of this material, either in or out of the soil, is very imperfectly known.

The isolation of carbohydrates from soil is at present confined to a single compound, a pentosan or a substance yielding a pentose sugar.

Nearly all soils when boiled with hydrochloric acid of moderate strength give furfural. The evolution of furfural when an organic mixture is heated with hydrochloric acid is usually regarded as evidence of the presence of pentosans. Pentosans are substances of a gummy nature and unknown constitution for which the formula $C_5H_8O_4$ is usually given; they gives on hydrolysis with acids pentose sugars, $C_5H_{10}O_5$, which are definit crystallin compounds of known constitution. These pentose sugars on further heating with acids give furfural, the amount of furfural being proportional to the amount of pentosan or pentose. Based on this fact a method has been devised for determining the pentosan by determining the amount of furfural obtained under certain conditions. This method is adopted as a provisional one by the Association of Official Agricultural Chemists.[1]

The method, when applied to soils, generally gives weighable quantities of the phloroglucide, the form in which the furfural is determined. The figures given below show results obtained by this method applied to ten soils of widely different types and character of organic matter. Ten grams of soil were used, boiled with 12 per cent. hydrochloric acid and the distillation carried on in the usual manner until there was no further evolution of furfural, which was usually the case when the distillate amounted to 300 or 400 cc. The furfural was determined as phloroglucide and the calculation made according to the formula in the provisional method cited.

The figures given here illustrate well, perhaps better than any others available, the great variation of organic matter in soils. In these ten soils selected somewhat at random the pentosan carbon per 100 of total carbon varies from 1.30–28.53, while the third lowest result, 1.83, was obtained from a soil containing the largest quantity of organic matter.

Susquehanna clay loam	1.048	0.659	0.299	28.53

The Marshall loam containing the largest quantity of pentosan, 2.75 per cent., was selected for further investigation. The soil was from North Dakota and the sample was taken from a field that had grown flax for a number of years. There had been no direct addition of straw or other pentosan-containing material other than that incidental to the growing and harvesting of the crop. An alkaline extract of this soil was made by treating it for several hours with 2 per cent. sodium hydroxide, the dark-colored extract was siphoned off and the humus compounds precipitated by acidifying with acetic acid, the filtrate made neutral and filtered from the precipitate formed. Lead acetate in excess was added to the neutral filtrate, resulting in the formation of a heavy brown precipitate and the removal of nearly all the color from the solution. To the filtrate from this precipitate dilute ammonia was carefully added, when a light yellow, voluminous precipitate was formed. This, after washing, was suspended in water and treated with dilute suphuric acid, avoiding excess. The lead sulphate was removed by filtration and the filtrate concentrated to a small volume. To this solution three volumes of 95 per cent. alcohol were added, when a gummy precipitate was formed which after washing with alcohol dried to a hard, translucent mass. This mass contained traces of lead which it retained very persistently. It was soluble in alkalies and formed an opalescent mucilage with water. On heating with 12 per cent. hydrochloric acid, furfural was given off freely and on heating with phloroglucinol and hydrochloric acid the characteristic purple color reaction for pentose sugars was obtained. On digesting for some time with sulphuric acid of moderate strength and neutralizing, a solution was obtained which reduced Fehling's solution and gave an osazone melting at 160–161°. On treating with cadmium carbonate and bromine according to the method of Bertrand,[1] the characteristic crystals of the double salt cadmium xylonate and cadmium bromide were obtained, showing the presence of xylose as one of the products of hydrolysis of the substance isolated from the soil. Tests made for the presence of other pentose sugars gave negative results.

---

[1] *Bull. soc. chim.*, [3] 5, 556 (1891).

The quantitative method of determining pentosan depends as has been noted on the formation of a pentose from the pentosan and the formation of furfural from the sugar on further heating with acid. In the cell wall material which makes up such a large portion of the organic matter of plants no doubt there is a pentosan compound present, either as such, or as part of the complicated molecule of lignocellulose, for a crude pentosan can be prepared from such material. In the case of the Marshall loam such a crude pentosan was obtained and was probably present as such in the soil as a plant residue. In the case of soil organic matter in general, however, it cannot be assumed that the formation of a pentose sugar and from it furfural, necessarily indicates the presence of a pentosan as such. Pentose sugars are part of the complicated molecule of nucleoproteins and phosphatides and are split off from these on heating with acids. The nucleoproteins are characteristic of tissues in which nucleated cells are abundant and those of animal origin have been especially studied. The investigation of those of plant origin is not so thorough, but there is every evidence that the parts of plants rich in cells are also rich in nucleoproteins and this compound and its decomposition products must contribute to the organic matter of the soil.

With this in mind it is evident that a determination of pentosan in soil by the method in general use is simply the determination of the furfural that may arise from a pentosan, a pentose, or a pentose-yielding material other than a pentosan.

In the light of our present knowledge of pentosans and pentose-yielding material, their presence in a soil must be regarded either as a plant residue, such as a portion of the lignocellulose, which has resisted decomposition, or as products of decomposition of complicated compounds such as nucleoproteins.

[FROM THE LABORATORY OF PHYSIOLOGICAL CHEMISTRY OF THE DEPARTMENT OF ANIMAL HUSBANDRY OF THE UNIVERSITY OF ILLINOIS.]

ON THE PRESERVATION OF FECES.

BY PAUL E HOWE, T. A RUTHERFORD AND P. B. HAWK

Received September 27, 1910

Fresh feces lose nitrogen when subjected to a drying process, even when such process is carried out under the most carefully controlled conditions. Of late years this fact has come to be generally recognized and consequently various schemes have been adopted in the attempt to determin the amount of this lost nitrogen in order that a correcting factor might be applied. None of these forms of manipulation, so far as we are aware, has proved entirely satisfactory. As a result of a series of tests Zaitschek[1] concluded that the loss of nitrogen in drying feces was greater for the feces of carnivora than for those of the herbivora. He further found that drying feces with added acid did not always wholly prevent a loss of nitrogen and that entirely accurate results could only be obtained by determining the nitrogen content in several samples of fresh feces. The extent of the nitrogen loss, according to this investigator, depends on the quantity of non-protein nitrogen present, as well as upon the moisture content of the feces.

In our experiments the feces were collected in the ordinary friction-top paint pail which had previously been rinsed with a 10 per cent. alcoholic solution of thymol and subsequently dried. During the preservation period these pails were kept in a refrigerating room. The feces were analyzed for nitrogen and moisture. In some of the tests, the data from which are given below in tabular form, the stools were analyzed immediately after defecation and at short intervals thereafter. In other tests the stools were collected from a subject through a period of eight days and this carefully mixed eight-day sample was then subjected to analysis, the initial analysis being followed by others at long intervals. In some instances the tests covered a period of two hundred and forty-eight days after the dropping of the stool.

In Table I we have data from two samples collected from two different individuals living on similar diets, the feces being collected through an eight-day period as just indicated. An examination of the data from stool No. 1 shows that there was practically no change in the nitrogen value of the sample even after 158 days in the refrigerating room. From this time to the end of the experimental period of 248 days there was a slight lowering of the nitrogen content. In the case of the moisture content of this stool the data indicate that there was practically no change in the moisture value for a period of twenty-one days. On the one hundred and fifty-eighth day the moisture had increased about 3 per cent. Unfortunately no analyses were made during the period intervening from the 21st to the 158th day. Stool No. 2 analyzed at the same intervals as stool No. 1 yielded similar data.

Data from the analyses of three individual stools dropped by three men living on different diets are given in Table II. The initial analysis was in each instance made seven hours after the stool was passed, this first analysis being followed by other analyses at intervals of 2, 4 and 8 days. In one instance (stool No. 4) the final analysis was made on the 83rd day. Each stool yielded a very uniform series of values for both nitrogen and moisture throughout the experimental period of eight days. At the 83rd day stool No. 4 was found to have gained moisture (5–6 per cent.) and to possess a lower nitrogen content. In Table III are given data from 3 other individual stools which were collected under similar conditions as those mentioned in Table II and dropped by the same individuals. The procedure in the case of the stools differed from that adopted in the case of the stools mentioned above in that the first analysis was made upon the fresh stool. The stools were passed, immediately mixed, sampled and portions weighed out for analysis. The analysis of the fresh feces was followed by the further examination of the stool at intervals of 2, 5 and 7 days. An examination of the table will show a most satisfactory uniformity in the values obtained from the different analyses.

---

[1] *Arch ges. Physiol.*, 98, 595 (1903).

Data from composit stools are again given in the Table IV. This table includes data from 6 composit stools analyzed at intervals of 8, 43 and 92 days. These samples were from 6 different men living upon a similar diet, the individuals being different from those previously mentioned. At the end of the forty-third day the nitrogen and moisture values (with the exception of those of stool No. 10) were found to be rather uniform with those obtained at the initial analysis.

Conclusions.

I. The method of feces collection and preservation which involves the use of friction-top pails is very satisfactory for the following reasons:

1. It permits of the analysis of the *fresh* feces.

2. It prevents loss of moisture.

3. It maintains the nitrogen content practically unaltered for at least *twenty days* and frequently for a much longer period.

4. It eliminates all loss of material since the feces are not transferred to any other receptacle before they are thoroughly mixed for analysis.

II. It is preferable to make the analysis on the *fresh* feces, since this procedure does away with all drying processes and hence eliminates the loss of nitrogen which invariably accompanies such drying.

STUDIES ON WATER DRINKING.[1] III. ON THE URIC ACID ELIMINATION FOLLOWING COPIOUS WATER DRINKING BETWEEN MEALS.

BY S. A. RULON, JR., AND P. B. HAWK.

Received October 18, 1910.

The present paper embraces a report of two metabolism studies made upon two individuals, the topic under consideration being the determination of the influence of large volumes of water taken *between* meals upon the uric acid output. The subjects were young men 24 and 29 years of age respectively. They were placed upon uniform diets containing a small amount of water and were brought into nitrogen equilibrium, after which an interval elapsed during which large volumes of water were daily added to the uniform diet, the added water being taken *between* meals. This period of high water ingestion was then followed, in each instance by a period throughout which the uniform diet and low water ration of the preliminary interval were fed. In the first experiment the three periods of the test were 3, 4, and 2 days in length respectively, whereas in the second experiment the periods were 3, 2, and 4 days in duration. The daily diet, during the first study, consisted of 2100 grams of whole milk, 120 grams of butter and 300 grams of crackers, this ration being divided into 3 equal portions and fed at the customary intervals. The ration of the second study was 1800 grams of whole milk, 75 grams of butter and 330 grams of crackers. During the interval of copious water ingestion of the first experiment, the volume of water daily ingested was 5900 cc. as against an ingestion of 400 cc. per day during the preliminary and final periods. These volumes were 5,000 cc. and 500 cc. respectively in the second experiment. In other words the water ingestion was increased $5^1/_2$ liters in the first study and 5 liters in the second study. The body weights of the subjects were about the same (60.6 kg. and 61.5 kg.). During all of Experiment II and for 3 days of Experiment I, the urine was collected in 24-hour samples. The urine specimens for the remaining days of the first experiment were daily collected in 5 sub-periods, there being four $3^1/_2$-hour periods and one ten-hour period. The $3^1/_2$-hour periods began at 8 a.m. and extended from that hour until 10 p.m., the 10-hour period extending from 10 p.m. until 8 a.m. the following day. The urine samples were preserved by thymol powder. Uric acid was determined by the Folin-Shaffer method.[1]

---

[1] For I and II of this series of studies see Hawk, *University of Penn. Med. Bull.*, 18, 7 (1905); and Fowler and Hawk, *J. Exp. Med.*, 12, 388 (1910), respectively.

Copious Water Drinking and Uric Acid Output.

The data from the first experiment are given in Table I. An examination of that table shows that there was 0.319 gram of uric acid excreted upon the first day of the experiment and that this was followed on the remaining two days of the preliminary period by daily eliminations of 0.294 gram and 0.267 gram respectively. When the large volume of water was introduced into the organism, however, there was a decided lowering of the uric acid values. The data indicate that the quantitative examination of the urines for the 4 days of copious water ingestion yielded values of 0.195, 0.131, 0.150 and 0.148 gram respectively. The final period in which small amounts of water were again daily ingested was accompanied by a return to the normal uric acid level of the preliminary period. These data would seem to indicate, then, that the ingestion of large amounts of water is accompanied by a pronounced decrease in the uric acid elimination. (This question is further discussed in a later paragraph.)

---

	4	0.033		215	
	5	0.063		315	
IX			0.279		790

A consideration of the uric acid output for the daily sub-periods of the first experiment fails to reveal any uniformity in the uric acid elimination for the different days. In some instances the maximum excretion occurred during the first $3^1/_2$-hour period, whereas on certain other days the second, third, or fourth sub-period, as the case may be, included the maximum yield. It is of interest that the largest urine flow was found to occur during the second sub-period on each day of the interval of high water ingestion. This uniformity did not hold for the preliminary or final periods. No relation was noted between the volumes of the urine fractions and their uric acid content.

TABLE II.—URIC ACID EXCRETION. EXPERIMENT II.

Day of experiment.	Urine data Uric acid content.	 Volume.	Water ingested.[1]
	Preliminary Period (3 Days).		
	Gram.	cc.	cc.
1	0.282	1090	500
2	0.267	997	500
3	0 274	770	500
	Water Period (2 Days).		
4	0 279	5250	5000
5	0 258	5800	5000
	Final Period (4 Days).		
6	0.261	1275	500
7	0 283	1160	500
8	0 254	1140	500
9	0 268	885	500

When we examine the data from the second experiment, as given in Table II, we find that the conditions during the interval of high water ingestion were entirely different from those which were observed in the similar period of the first study. The daily uric acid output for the preliminary period, however, was very similar to that already discussed in connection with the data from Experiment I. This logically follows from the fact that the subjects were of practically the same body weight and were being fed a very similar ration. The values for the period range from 0.267–0.282 gram per day. The initial day of the water period was accompanied by an increase of $4^1/_2$ liters in the water ingestion. Bearing in mind the uric acid findings of the first experiment, we would expect to observe an accompanying lowering of the uric acid output. However, the data indicate that no such decrease occurred in this case, inasmuch as the daily uric acid excretion for each day of the water period was an approximate duplication of those obtained during the low water ingestion of the preliminary period. When we pass to the final period with its normal water ration, we again fail to note any considerable or significant variation in the uric acid values.

Going no deeper into the question than a comparison of the analytical data obtained in the two experiments, it seems that copious water ingestion in the case of one subject caused a pronounced decrease in the daily output of uric acid, whereas in the case of the other subject similar experimental manipulation was productive of no alteration in the course of the uric acid elimination. With no other data at hand, then we would interpret the lack of uniformity observed as due to individuality. When we consider the known facts regarding the origin and excretion of uric acid, however, it is difficult to see how an increased water ingestion can be considered as a logical forerunner of a decreased uric acid excretion. To be sure, Genth[1] as far back as 1856 did obtain a lowered uric acid output after feeding a ration which embraced a comparatively high water intake. However, Genth used the Heintz method for the determination of his uric acid values, a method which is considered inaccurate. Later Schöndorf[2] using Salkowski's modification of Fokker's method secured data which indicated a slightly lowered excretion under the influence of high water ingestion.

---

[1] Exclusive of the water content of the milk.

On the other hand Laquer[3] and Schreiber[4] have each shown a slightly increased excretion of uric acid after feeding from 1–3 liters of water.

Recent tests made by us have indicated quite conclusively that the Folin-Shaffer procedure does not always yield the total uric acid output of urines which possess as low specific gravities as those obtained during the water periods of our experiments, *i. e.*, 1.003–1.010. For this reason we are not willing to interpret the data from our first experiment as indicating that copious water drinking has caused a decrease in the uric acid elimination, but are rather inclined to believe that a portion of the uric acid content of those urines of low density escaped determination by the Folin-Shaffer technic. It is possible that the factor of individuality has also exerted an influence, but we place more reliance upon the quantitative data obtained in our second experiment which show *no change* in the uric acid output under the influence of the ingestion of large volumes of water. We believe the data there set forth represent the true relations for this subject and that the urines were of such a character as to permit the securing of accurate data by means of the Folin-Shaffer procedure.[5] The values obtained for the water period of the first experiment we believe are too low and do not represent the absolute uric acid values for those days. Why the dilute urines from one subject should yield accurate data and similar urines from another subject should yield data apparently inaccurate when the same procedure was used in the two instances, we are unable to say. No interfering substances could be demonstrated to be present and it is rather difficult to see just how the urines from the two experiments could differ much in general characteristics, inasmuch as the dietary of each experiment was made up of the same constituents.

---

[1] Genth, Quoted by Schöndorf, *Arch. ges. Physiol.*, 46, 529.

[2] Schöndorf, *Arch. ges. Physiol.*, 46, 529.

[3] Laquer: Kongress für innere Medicin, 1896, p, 381.

[4] Schreiber, "Die Harnsäure," 1899, p, 38.

[5] It may be, of course, that the Folin-Shaffer method also failed to determin the total uric acid content of these urines. In that event an increased excretion of uric acid must have followed copious water drinking.

Summary.

Two experiments were made to demonstrate the influence of copious water drinking *between* meals upon the uric acid output. The subjects used were two young men 24 and 29 years of age respectively. Each experiment was divided into three periods, a preliminary period during which nitrogen equilibrium was established through the feeding of a uniform diet, a water period during which this uniform diet was supplemented by the daily drinking of a large volume of water *between* meals, and lastly a final period in which the dietary regimé of the preliminary interval was in force.

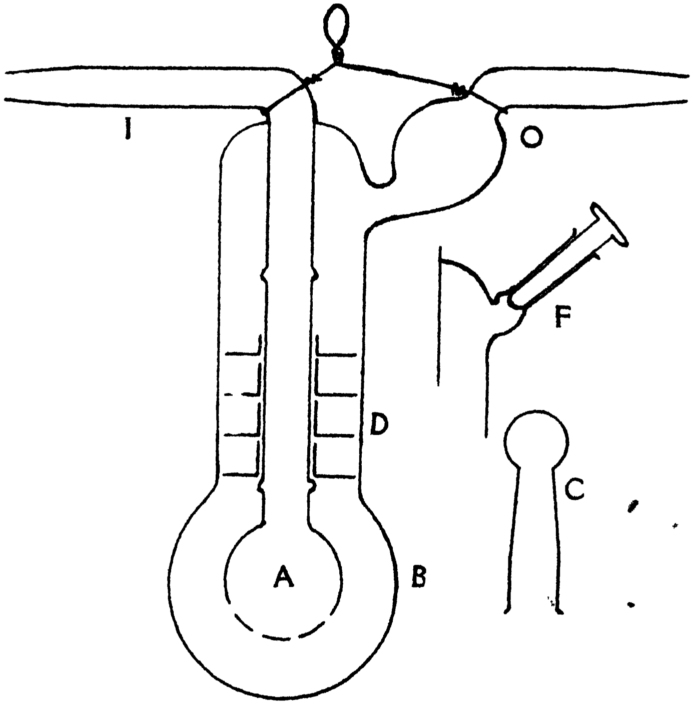
In one experiment copious water drinking caused no change in the uric acid output, whereas a pronounced decrease in this excretion was observed in the case of another subject. The data indicating a decreased elimination of uric acid under the influence of copious water drinking we believe to be due to the fact that the Folin-Shaffer procedure did not, in the case of this subject, determin the total uric acid content of those urines of extremely low density, *i. e.*, 1.003–1.010. This interpretation has been substantiated by tests made in another connection.

Upon those days when the urine for the twenty-four-hour interval was collected in five sub-periods, there was apparently no relation between the urine volume for the sub-period and the uric acid content. There was likewise no uniformity in the daily course of the uric acid excretion, the maximum output occurring on different days in the first, second, third, and fourth sub-periods respectively. The maximum urine flow occurred uniformly in the second sub-period of those days on which large volumes of water were being ingested. This uniformity was not observed on the days of low water ingestion.

URBANA, ILL.

NOTE.

A Convenient Potash Bulb.—More than a year ago the writer devised a potash bulb much like the one shown in the cut, and it proved to be so convenient and efficient that it was thought worth while to describe the no less efficient and much more convenient form shown. The cut is drawn to scale from one now in use. The inner and outer tubes, A and B, are made of very thin "condenser" tubing, the tubes I and O being of ordinary thickness. The essential feature is the disks, D, which fit so loosely between A and B that they can move freely up and down between the projections blown in the wall of A. The annular free spaces should be not less than 1 mm. broad. The disks are made by abruptly flaring glass tubing of proper bore and cutting off about 4 or 5 mm. from the end.



When gas is entering through I, it is first broken up into small bubbles on passing through the openings in A. (Instead of being blown into a bulb, the end of A may be flared to form a broad disk.) It is then trapped in succession by the disks which, when working properly, alternately rise and fall, continually wetting the walls of B with fresh solution. The lowest disk must not fall below the cylindrical part of B, and the uppermost must stop rising at least a centimeter below the outlet. The amount of liquid to be used depends on its viscosity and the rate of flow of the gas. Enough to just reach the second disk is usually sufficient. The cleanest way to introduce it is through the filling-tube, F, set on in a plane at right angles to that of I and O. The ground-in stopper is made of glass rod, and is rendered perfectly tight by means of stopcock grease.

In weighing, the caps, C, are placed on I and O, and the tube is suspended by means of a permanently attached loop of platinum wire, as shown.

This form of absorption bulb is less fragile than the Geissler bulb, has a much smaller surface and is considerably lighter. When filled it weighs from 35-40 grams. The method of filling obviates all danger of contact between the solution and the rubber connections. C. E. WATERS.

BUREAU OF STANDARDS, WASHINGTON,
September 29, 1910.

NEW BOOKS.

A Manual of Volumetric Analysis, Treating on the Subjects of Indicators, Test-papers, Alkalimetry, Including Assay of Drugs by Titration, Acidimetry, Analysis by Oxidation and Reduction, Iodimetry, Determinations by Precipitation, and by Color Comparison. By VIRGIL COBLENTZ, PH.D., Pharm. M, F.C S., Professor of Chemistry in the New York College of Pharmacy. Second edition, revised, completely reconstructed and enlarged by Anton Vorisek, Phar. D., Professor of Analytical Chemistry in the College of Pharmacy Columbia University, in the City of New York, with 37 illustrations. Philadelphia: P. Blakiston's Son & Co., 1012 Walnut Street. 1909.

"Denn was man schwarz auf weiss besitzt kann man getrost nach Hause tragen." While this suggestion was given by Mephisto to what was presumably a German student, the average American student does not have the time, or at least he thinks he has not the time to take notes for the purpose of taking them home. Neither is he content, as a rule, with such a large text as Sutton or Mohr that can be consulted in the departmental library. He is happiest when he has a textbook that does not contain much more than his immediate necessities demand.

This manual of volumetric analysis meets such a demand and meets its acceptably. Considerable information is crowded between the two covers.

In the first edition the ionic theory was applied to indicators only. In this the second edition it "has been extended to chemical reactions other than those of the indicators." Evidence of this extension is rather scarce in the text, being restricted mainly to a few pages in the chapter devoted to "Determinations by Neutralization."

"The didactic system (H = 1,000) of atomic weights used in the first edition has been dropped and replaced by the atomic weights of the International Committee of Atomic Weights. However, the rounded value of H = 1.01 for the official value 1.008 was adopted "to shorten long fractions and to facilitate calculations."

The book will, no doubt, continue to find many friends among students and teachers. EDWARD KREMERS.

History of Chemistry. By SIR EDWARD THORPE. Two volumes, 16mo., illustrated. Vol. 1, pp. xii + 195; Vol. 2, pp. vii + 202. New York: and London: G. P. Putnam's Sons. Price, cloth, 75 cents per volume.

These two volumes by the author of "Essays in Historical Chemistry" form a part of a series of books on the "History of the Sciences," the

"History of Astronomy" by George Forbes having previously appeared.

In the study of the natural sciences there is perhaps no part that is more commonly slighted or neglected than their history. Unfortunately this is still especially true of the history of chemistry. The study of the history of the development of the natural sciences is not only intensely interesting, but it offers rare opportunity to acquire breadth of view and culture, for the growth of scientific thought and methods is most intimately connected with the progress of mankind. No one can really fully appreciate what we know of chemistry without at least a rudimentary knowledge of the history of that science. But very few students of chemistry have read the monumental work of Kopp on the history of chemistry from cover to cover, indeed not many have read through the less comprehensive books like those of Ernst von Meyer or Ladenburg. Most students are so much engrossed with the work of mastering the science itself that they neglect its history, a study of which would not only clear up many difficult points, but would act as a source of inspiration for further vigorous efforts.

The present brief history of chemistry may be highly recommended to the student. It is written in a clear, interesting style, which can not fail to captivate the reader. The first volume traces the history from earliest times to the middle of the nineteenth century, and the second volume treats of the period from 1850 to the present day. The author presents the origin and growth of chemical views and theories as based upon experimental investigation. Considering the space allotted, he has succeeded very well on the whole, though to be sure it was necessary to greatly curtail many of the interesting phases of the history of the science. The volumes contain twenty-five portraits of noted chemists. Some of these have been printed for the first time. One of the special features of the volumes is that they contain many short biographical sketches of men prominent in the development of chemical ideas. In these sketches the author is at his best, as indeed one would expect from his "Essays in Historical Chemistry," which are classics. If any criticism is to be made on the books, it would be that these biographical sketches occupy too much space as compared with that devoted to the tracing of the development of chemical theories.

It is to be hoped that these volumes will stimulate renewed interest in the history of chemistry. May they act as an inspiration to the student of science and lead him to delve further into the more exhaustive treatises on chemical history, a study of which is indispensable to every one who really desires a thorough understanding of the chemical facts, laws, and theories that have thus far been accumulated.

The books are neatly bound in cloth, the paper is good and the print clear.
LOUIS KAHLENBERG.

Neuere Anschaungen auf dem Gebiete der anorganischen Chemie. By PROF. DR. A. WERNER. Second Edition Braunschweig. Friedrich Vieweg und Sohn. 1909. pp xv + 292. Price, 9 Marks; bound, 10 Marks

To the average chemist only a limited time is available for familiarizing himself with the details of developments in lines other than his own. The appearance of the first edition of this book in 1905 was therefore welcomed by all who had become interested in the remarkable work of Werner and his co-workers, yet who had gotten only a hazy idea of the subject, on account of the enormous mass of material appearing constantly in the journals. Since then the number of contributions to the literature has not grown less, rather has it increased. This has been due to the extension of the views developed from the study of the metal-ammonia compounds to the hydroxy compounds, basic salts, acids, bases, hydrolysis, dyestuffs, and the difficult but successfully exploited field of the polynuclear compounds. Consequently a new edition of the book has become necessary, and in this second edition the author has brought together in concise form, and with full bibliography, all of the later developments in this fascinating chapter of inorganic chemistry.

Based upon the experience gained from the first edition, the arrangement of the matter has been greatly improved, making the book much more readable to those unfamiliar with the subject.

The new edition shows clearly the development of the author's views concerning valence. His attitude from the outset has been that of one who puts forth no final solution of a problem, but rather a working hypothesis based upon a clear insight into relations among a mass of compounds hitherto considered inarticulate. His hypothesis of "secondary" or "auxiliary" valences has indicated the way for experimental work leading to the discovery of many new compounds, explained the constitution of many old ones, and demonstrated relations hitherto unrecognized. Doubtless, as the author himself believes, the final truth concerning these compounds has not yet been revealed; but certainly his views and work constitute a most important step toward that truth.

The diversified character of the developments in this complex subject can be understood only when it is known that the author, while possessing a fine scientific imagination, is also an indefatigable worker in the laboratory; that while interested primarily in inorganic, he is equally at home in physical and in organic chemistry.

It is to be hoped that at some early day Prof. Werner will publish a laboratory manual embracing the preparation of typical compounds in each important group, and especially the methods employed in passing from one group to another. Such laboratory directions exist, of course, in the literature, but they are so widely scattered that many turn aside from work in this field. The reviewer can imagine no more attractive subject for a student course in inorganic preparations than, for example, the cobaltammines, with their varying colors, their differences in ionization, and the multiplicity of possible transformations.

CHAS. H. HERTY.

Die Alkaloide. Eine Monographie der natuerlichen Basen. Von DR. ERNST WINTERSTEIN, Professor, und DR. GEORG TRIER, Assistant, an der eidgenössicschen polytechnischen Schule in Zurich. Verlag von Gebrüder Bronträger, Berlin, 1910.

The appearance of this book is very timely. While text-books on organic chemistry usually contain a short chapter on alkaloids, special treatises on this subject are few and appear at long intervals. The book is excellently gotten up from the standpoint of workmanship, and contains almost every alkaloid whose existence has been definitly established. By omitting detailed methods of manufacture, leaving out descriptions of alkaloidal salts, and cutting down bibliographic references to a minimum, the authors have managed to condense a vast subject into 340 pages. A special feature of the book is the special attention given to the physiological behavior of those alkaloids whose effect on living organisms has been tested. The book consists of a general introduction, a special part and a large chapter on the function and generation of organic bases in plants. The introduction consists of ten chapters: Definition; historical review; occurrence; general methods of preparation, detection and quantitative estimation; general properties; constitution and methods used for its determination; synthesis of alkaloids; physiological behavior; phytotoxins; relation between constitution and physiological action; classification. The authors distinguish between alkaloids in general and alkaloids proper. The first term applies to all nitrogenous bases found either in vegetable or animal organisms; the second is restricted to vegetable bases containing nitrogen in heterocyclic union and possessing physiological activity. In the chapter on physiological activity the supposition is advanced ascribing this activity to a molecular combination of alkaloid and protoplasm, the enormous effect of relatively small doses being due to the smallness of the molecular weight of the organic bases as compared with the exceptionally large molecular weight of the albumins. A thorough discussion is given of the remarkable tolerance of some animals towards poisonous bases, atropine, for example, having no effect upon the rabbit, and the lethal dose of morphine being ten times larger for chickens and a thousand times larger for goats than for man. The authors criticize the utility of antidotes whose action, like that of tannin, consists in the formation of insoluble combinations with the organic base. Since many alkaloids exist in the poisonous plants in the form of tannates, the administration of tannin cannot be expected to destroy the toxicity of the bases. In the chapter on the relation between constitution and physiological action, the authors, after enumerating the well-established regularities, arrive at the conclusion, expressed in the words of Schmiedeberg, that it will be more difficult to establish a scientific theory of this relation than of that between constitution and color. In the special part no attempt is made to classify the alkaloids according to any definit system. The aliphatic bases are treated first, then comes in succession the aromatic with an aliphatic side chain, pyridine, quinoline and isoquinoline derivatives, bases containing several nitrogen atoms in the molecule and finally the alkaloids of unknown constitution. In the voluminous chapter on the function and generation of alkaloids in the plants the authors review the various proposed theories, and express their preference for the supposition that the vegetable bases are catabolic products of the albumins, and that their formation has no other purpose than the removal of nitrogenous decomposition products that have become useless or even harmful to the living plant. Pictet's general theory of the formation of the alkaloids from certain so-called protoalkaloids of simple constitution which are themselves decomposition products of the albumins is accepted in its general features, but it is shown that, contrary to that theory, formaldehyde cannot be regarded as the direct methylating agent, and that Pictet's scheme of the formation of alkaloids with a pyridine nucleus from pyrrole is not quite satisfactory. The objection to formaldehyde as a direct methylating agent is based, among other considerations, upon the fact established by Winterstein that alkaloids are frequently formed in seeds during germination in the dark when there is no photosynthesis to produce formaldehyde. The authors think that the direct methylating agent is methyl alcohol which, however, may in some cases owe its formation to the aldehyde produced primarily. The alkaloids containing a pyridine nucleus are formed not from pyrrole, but from lysine produced in the splitting up of the albumins. Even the nitrogen-free groups, like benzoyl, cinnamyl, etc., frequently present in the molecule of alkaloids, are produced from the amino acids of the albumins by a reaction similar to the one called by Ehrlich "alcoholic fermentation of amino acids." An important role in the formation of alkaloids is ascribed to the betaines the constitution of which is assigned to several bases, *e. g.*, guvacine and arecaine, which hitherto were not supposed to be betaines. The authors' views are illustrated by many examples showing the genetic relations between the albumins and the alkaloids. A characteristic feature of the successive phases of the transformation of the former into the latter consists in the destruction ("blocading") of the reactivity of the hydrogen atoms of the amino groups by reactions of methylation or, in some cases, condensations with alcohols, phenols or aldehydes. For this reason the authors propose a new definition of alkaloids as "organic compounds produced in the formation or transformation of protoplasmic substances (proteins, proteids, phosphatides, etc.) in such a way that the reactive hydrogen atoms of the basic groups are closed, so that the resulting products are unable to regenerate the original or to form new protoplasmic substances." The presence of choline and of purine bases in the molecules of the albumins is ascribed to the action of ammonia on some of the nitrogen-free intermediate products of photosynthesis. The book is full of suggestions and deserves a prominent place in every well-equipped library. H. M. GORDIN.

Weg? (Schumann), 252, Einführung in die qualitative chemische Analyse zum Gebrauch bei den prakt. Uebungen im Laboratorium (Wiechowski), 253; Beilsteins Anleitung zur qualitativen Analyse (Winterstein, Trier), 254; Chemisches Praktikum (qualitative Analyse) für höhere Lehranstalten (Wolland), 254; Outlines of Qualitative Chemical Analysis (Gooch, Browning), 428; A Manual of Qualitative Chemical Analysis (McGregory), 429; Die Bestimmungsmethoden des Wismuts und seine Trennung von den

Anderen Elementen (Moser), 429; An Elementary Treatise on Qualitative Chemical Analysis (Sellers), 430; Praktikum der quantitativen anorganischen Analyse (Stock, Stähler), 430; La réfractométrie et ses applications pratiques (Sidersky), 576; Commercial Organic Analysis (Allen), 726; Manuel théorique et pratique d'analyse volumetrique (Duparc, Basadonna), 727; Anleitung zur organischen Elementaranalyse (Henle), 727; Chemisch-technische Untersuchungsmethoden (Lunge, Berl), 728; Uebungsbeispiele zur quantitativen Analyse (Meigen), 728; Anleitung zur quantitativen chemischen Gewichtsanalyse nach C. Zimmermann (Pechmann), 1010; Die Methoden der Massanalyse (Beckurts), 1110; Theoretical Principles of the Methods of Analytical Chemistry Based upon Chemical Reactions (Chesneau), 1110; Qualitative Analysis, Tables for Use at the Bench (Lewis), 1111; Quantitative Analysis (Treadwell), 1112; Qualitative Chemical Analysis, Organic and Inorganic (Perkin), 1365; Uebungsbeispiele aus der quant. chem. Analyse (Vortmann), 1366; Tabellen zur chemischen Analyse (Wallach), 1366; Anleitung zur vereinfachten Elementaranalyse für wissenschaftliche und technische Zwecke (Dennstedt), 1537; Einleitung in die Chemische Analyse (Medicus), 1538; Lötrohrprobierkunde (Henglein), 1698; A Manual for Assayers and Chemists (Seamon), 1699; La réfractométrie et ses applications pratiques (Sidersky).. 1699

Organic: Ueber das Verhalten einiger aromatischer Essigsäure- und Glykollderivate tierischen Fermenten gegenüber (Minkowski), 251; Die orientierenden Einflüsse und der Benzolkern (Obermiller), 251; Formaldehyd (Orloff), 251; Introduction to the Preparation of Organic Compounds (Fischer), 428; Modern Organic Chemistry (Keane), 429; Contributions à la connaissance des oxyaldéhydes orthovanilline et l'aldehyde orthovératrique (Noelting), 429; Die Sulfosäuren des Anthrachinons und seiner Derivate (Goldberg, Friedmann), 576; Ueber α-Oxolaktame (Roschke), 576; Die Knallsäure (Wieland) 576; Ueber Oxalmalonsäureester (Heuser), 727; Systematic Practical Organic Chemistry (Norman), 728; Ueber Konstitution und Farbe der Chinonimine (Piccard), 728; An Introduction to the Study of Compounds of Carbon (Remsen), 728; Ueber die Bildung der Naphthene im Erdöl (Routala), 728; Ueber Synthesen ringförmiger Verbindungen mittels Dipropylmalonylchlorids und Succinylchlorids (Rothschild), 728; Practical Organic Chemistry (Sudborough, Campbell), 728, The Simple Carbohydrates and the Glucosides (Armstrong), 813; Einfluss der Lösungsmittel auf die Verteilung der Isomeren (Bruner, Vorbrodt), 813; Sur une association naturelle de dimethylanthracènes (Lavaux), 813; Les synthèses dans le groupe de l'indigo (Pozzi-Escot), 895; Untersuchungen über die Affinitäten. Ueber Bildung und Zersetzung der Aether (Berthelot, Péau de Saint-Gilles), 1008; Methoden der Organischen Chemie, 1009; Cours de chimie organique et biologique (Porcher, Nicolas), 1010; Jahrbuch der Organischen chemie (Schmidt), 1010; Die direkte Einführung von Substituenten in den Benzolkern (Holleman), 1111; Organische Chemie und die Lehre vom Leben (Wohl), 1112; Lehrbuch der organischen Chemie (Holleman), 1364; Ueber Nitrocumarine und ihre Konstitutionsermittelung (Landsberger), 1364; Outlines of Organic Chemistry (Moore), 1365; Die elektrolytischen Prozesse der organischen Chemie (Moser), 1365; A Method for the Identification of Pure Organic Compounds. Vol. 3. Identification of the Commercial Dyestuffs (Mulliken), 1365; Studien über Konstitutionsermittelung monohalogenisierter, mono- und dialkylierter Monoketone der Cyclohexanreihe (Steinhorst), 1366; L'acide thyminique (Duhamel), 1537; Elektrische Doppelbrechung der Kohlenstoffverbindungen (Leiser), 1538; Die Cellulose (Piest), 1539; Abbau des Morphobetains, II. Ueber einige Additionsprodukte cyclischer Basen mit Hydrochinon (Rettberg), 1539; Lexikon der Kohlenstoffverbindungen (Richter), 1539; Ueber die Reduktion von Pinen zu Pinan; Eigenschaften und chem. Verhalten des letzteren (Schenk), 1540; Die Alkaloide; eine Monographie der natürlichen Basen (Winterstein, Trier), 1540; Notions fondamentales de chimie organique (Moureu).............. 1699

Biological, Pharmaceutical and Foods: Bakteriologisches Taschenbuch, enthaltend die wichtigsten technischen Vorschriften zur bakteriologischen Laboratoriumsarbeit (Abel), 247; Die Auffindung der Gifte und stark wirkender Arzneistoffe (Autenrieth), 247; Elementary Photomicrography (Bagshaw), 247; Grundlagen und Ergebnisse der Pflanzenchemie (Euler), 248; Lehrbuch der Chemie für Pharmazeuten (Fischer), 249; Lehrbuch der chemischen Toxikologie und Anleitung zur Ausmittelung der Gifte, für Chemiker, Apotheker und Mediziner (Gadamer), 249; Repetitorium der pharmazeutischen Chemie (Gerke), 249; Biochemisches Taschenbuch (Glikin), 249; Der Tafelsenf (Mostrich) und die technische Verwertung der Senfpflanze (Hasterlik), 249; Lehrbuch der Pharmakognosie (Karsten, Oltamus), 250; Praktikum der Bakteriologie und Protozoologie (Kirskalt, Hartmann), 250, Analytisches Diagnostikum. Die chemischen mikroskopischen und bakteriologischen Untersuchungsmethoden von Harn, Auswurf, Magensaft, Blut, Kot (Kraft), 250; Phenol und seine Derivate als Desinfektionsmittel (Laubenheimer), 250; Die Beziehungen der Chemie zur Biologie und Medizin (Lockemann), 250; Dynamik der Oberflächen. Eine Einführung in biologische Oberflächenstudien (Michaelis), 251; Aids to the Analysis of Food and Drugs (Moor, Partridge), 251; Grundriss der Pharmakochemie (Oesterle), 251; Die Fermente und ihre Wirkungen (Oppenheimer), 251; The Vegetable Proteins (Osborn), 251; Lehrbuch der Pharmakologie (Poulsson), 252; Grundriss der Pharmakologie in Bezug auf Arzneimittellehre und Toxikologie (Schmiederberg), 252; Chemische Konstitution und physiologische Wirkung (Spiegel), 253; Methoden zur Untersuchung von Milch und Molkereiprodukten (Teichert), 253; Praktische Anleitung zur Ausführung des biologischen Eiweissdifferenzierungsverfahrens mit besonderer Berücksichtigung der forensischen Blut- und Fleischuntersuchung, sowie der Gewinnung präzipitierender Sera (Uhlenhuth, Weidanz), 253; Untersuchungen über "Antiformin," ein bakterienauflosendes Desinfektionsmittel (Uhlenhuth), 253; Spices and How to Know Them (Gibbs), 428; Die Bakteriologie des täglichen Lebens (Jaeger), 429; Ueber die chemische Durchlässigkeitlebender Algen- und Protozoenzellen für anorganische Salze und die spezifische Wirkung letzterer (Mengarini, Traube, Scala), 429; Selbstbereitung pharmazeutischer Spezialitäten (Mindes), 429; Schadliche Nebenwirkungen der Arzneimittel (Paczkowski), 429; Beiträge zur Photographie der Blutspektra unter Berücksichtigung der Toxikologie der Ameisensäure (Rost, Heise), 429; Die Erkennung von Blutflecken und die Unterscheidung von Menschen- und Tierblut in der Gerichtspraxis, zugleich eine Schilderung der Haupteigenschaften des Blutes, sowie der Blutverwandtschaft unter den Tieren (Schmidt), 430; Klinische Spektroskopie (Schumm), 430; Elements de chimie génerale, préparatoires à l'études biochimique des fermentations (Vandevelde), 430; Praktische Pharmazie (Fernau), 575; Physiologische Wirkungen der Benzoesaüre und des benzoesäüren Natrons (Gerlach), 575, Food Inspection and Analysis (Leach), 576; Handbuch der biochemischen Arbeitsmethoden (Abderhalden), 726, Outlines of Bacteriology (Ellis), 727; Ueber Vorkommen und Herkunft des Inosit im Tierkörper (Klein), 727; Chemie der Menschlichen Nahrungs- und Genussmittel (König), 727; Food Inspection. A Practical Handbook (MacEwen), 728; Handbuch der Biochemie der Menschen und der Tiere II Bd. 2 Hälfte: Biochemie der Gewebe und Organe (Oppenheimer), 728; Chemisches Praktikum für Mediziner (Rimbach), 728; The Proteins (Robertson), 728, Die Giftprüfung und die Konzession zum Handel mit Giften (Syllwaschy), 728; Lehrbuch der physiologischen Chemie (Hammarsten), 813; Les ferments protéolytiques Etude chimique et pharmacotechnique (Javillier), 813; Flüssige Krystalle, Myelinformen und Muskelkraft (Lehmann), 814; Toxikologische Chemie (Mannheim), 814; Beitrage zur Biochemie des Bodens (Moll), 814; Leitfaden der Milchhygiene (Schlossmann), 814; Conférences de pharmacie, Tome 4. Analyses d'urines, de fèces, de lait (Battegay), 895; Fabrication du chocolat (Fritsch), 895; Handbuch der biochemischen Arbeitsmethoden (Abderhalden), 895; Questions and Answers on Milk Testing (Publow, Troy), 895; Lehrbuch der Nahrungsmittelchemie (Röttger), 896; L'ambiente chimico ed i fermenti selezionati (Soucini), 896, Milch und Molkereiprodukte; ihre Eigenschaften, Zusammensetzung und Gewinnung (Sommerfeld), 896; Précis de chemie physiologique (Arthus), 1008; Il trattamento naturale ed artificiale delle acque da fogna, secondo i moderni sistemi di epurazione biologica (Ferrari), 1009; Chemische Untersuchung der Georgen-, Marien-, Wiesen-, Mariannen- und Friedrichs-Quelle zu Bad Landeck (Fresenius), 1009; Lehrbuch der Pharmakognosie (Gilg), 1009; Lehrbuch der physiologischen Chemie (Hammarsten), 1009, Die menschlichen Genussmittel, ihre Herkunft, Verbreitung, Geschichte, Bestandteile, Anwendung und Wirkung (Hartwig), 1009; Fleischvergiftungen und Paratyphusinfektionen, ihre Entstehung und Verhütung (Hübener), 1009; Die experimentelle Pharmakologie als Grundlage der Arzneibehandlung (Meyer, Gottlieb), 1009; Tossicologia forense (Muccioli), 1009; Nahrungsmittel-Chemie (Rottger), 1010; Lehrbuch der Physiologie des Menschen (Tigerstedt), 1010, Handbuch der Pharmakognosie (Tschirch), 1010; Methods Used in the Examination of Milk and Dairy Products (Barthel), 1110; Mikrophotographischer Wandatlas der Bakteriologie (Bujwid), 1110, Ergänzungstaxe zur Deutschen Arzneitaxe für 1910, 1110; Algemeine Chemie der Enzyme (Euler), 1110; Fermentazione e fermenti (Guareschi), 1111; Pharmazeutisch-technisches Manuale (Hell), 1111; Real-Enzyklopädie der gesamten Pharmazie (Moeller, Geisler), 1111; Analyse und Antidote der für den Arzt wichtigsten Gifte (Neumann), 1111; Arzneiverordnungen 1910. Die neuesten Arzneimittel und Spezialitäten (Rabow), 1111; Manual of Medical Jurisprudence, Toxicology and Health (Robertson), 1112; Hefen, Schimmelpilze und Bakterien (Bersch), 1363; Revue des médicaments nouveaux et de quelques médications nouvelles (Crinon), 1363; La chimie de matière vivante (Duclaux), 1363; Kurzgefasste Anleitung zu den wichtigeren hygienischen Untersuchungen (Fischer), 1363; Lehrbuch der Toxikologie für Tierärzte (Fröhner), 1363; Dealin, ein neues Antiseptikum (Hancken), 1364; Botanisch-mikroskopisches Praktikum (Kienitz-Gerloff), 1364; Die Fabrikation des Surrogatkaffees und des Tafelsenfes (Lehmann), 1364; Beitrag zur Kenntniss der Wirkung der Formaethrolpräparate (Liess), 1364; Examination of Water (Chemical and Bacteriological) (Mason), 1364; Die Untersuchung und Beurteilung des Wassers und des Abwassers (Ohlmüller, Spitta), 1365; Laboratory Notes on Industrial Water Analysis (Richards), 1365; Introduction to the Analysis of Drugs and Medicines (Nelson), 1365; Air, Water, and Food from a

Sanitary Standpoint (Richards, Woodman), 1365; Lehrbuch der Arzneimittellehre und Arzneiverordnungslehre (Tappeiner), 1366; The Compendium of Medicine and Pharmacy (Thompson), 1366; Nach Autoren und Sachnamen geordnete Sammlung der wichtigsten Reagenzien und Reaktionen für Chemie, Pharmazie, Physiologie usw. (Waldheim), 1366; Nouveaux éléments de pharmacie (Andouard), 1536; Elemente der physiologischen Chemie (Arthus), 1536; Das Wesen der Enzymwirkung (Bayliss), 1536; Guide pour les manipulations de chimie biologique (Bertrand, Thomas), 1537; Recherches sur l'épuration biologique et chimique des eaux d'égout (Calmette), 1537; Vergiftungen, Klinischen Teil. 2 Hälfte: Die organischen Gifte (Erben), 1537; Chemie und Physiologie der Milch (Grimmer), 1537, Die Vergiftungen (Jaksch), 1537; Die Arzneitherapie der Gegenwart (Kahane), 1538; Ueber das Wesen der Alkoholgärung (Kohl), 1538, Hilfstabelle für Nahrungsmittelchemiker (Kraus, Schwenzer), 1538; Mikroskopie und Chemie am Krankenbett (Lenhartz), 1538; Zur Frage von dem Einfluss der Milchnahrung auf den Stickstoff und Phosphorumsatz (Minz), 1538; Die Eisenbakterien (Molisch), 1538; Buchheisters Vorschriftenbuch für Drogisten (Ottersbach), 1539; Physical Chemistry, its Bearing on Biology and Medicine (Philip), 1539; Practical Sanitation (Reid), 1539; Ueber Bestimmungsmethoden der Cellulose (Renker), 1539; Handbuch der Milchkunde (Rievel), 1539; Kursus der physiologischen Chemie mit Anleitung zur qualitativen und quantitativen Analyse des Harns (Rosanow), 1539; Lehrbuch der pharmazeutischen Chemie. Teil I· Anorganischer Teil (Scholtz), 1539; Methoden der chemische en microscopische Diagnostick (Steensma), 1539; Cours de chimie physiologique et pathologique (Strzyzowski), 1540; Arbeiten aus dem pharmazeutischen Institut der Universität Berlin (Thoms), 1540; Ueber das Verhalten der Alkaloide in den Organen der Atropa belladonna L (Trögele), 1540, Contribution a la connaissance de divers phénomènes oxydasiques naturels et artificiels (Wolff), 1540; Ueber die Bindung der Derivate des Jods an das Gewebe der Leber (Wyssozky), 1540; Handbuch der Biochemie des Menschen und der Tiere, 1698;
Atlas der Krystallformen und der Absorptionsbänder der Hämochromogene (Dilling), 1698
Organanalytische Untersuchungen über dem Stickstoff- u. Phosphorstoffwechsel u. ihre gegenseitigen Beziehungen (Grund), 1698, Bakteriologisch-chemisches Praktikum (Prescher, Rabs) 1699

Metallurgical and Mineralogical: Die binären Metallegierungen (Bornemann), 248; Der basische Herdofenprozess (Dichmann), 248; Spezialstähle in Theorie und Praxis (Giesen), 249; La métallurgie électrique (Graffigny), 249, The Theory and Practice of Enamelling on Iron and Steel (Grünwald), 249; Metallographie (Guertler), 249; Igneous Rocks (Iddings), 249; Laboratory Notes on Iron and Steel Analysis (Macfarlane), 250, The Recognition of Minerals (Moor), 251; Eisenreduktion in Puddelofen (Otto), 251; Die Herstellung von hochprozentigen Ferrosilicium im elektrischen Ofen (Pick, Conrad), 252; Zink, Zinn, und Blei (Richter), 252; Tabellen zur Bestimmung der Mineralien mittels ausserer Kennzeichen (Weisbach), 253; The Metallurgy of Common Metals, Gold, Silver, Iron, Copper, Lead and Zinc (Austin), 428, Gold Refining (Clark), 428; Die Legierungen (Fermum), 428; Analyse des métaux par electrolyse. Métaux industriels; alliages, minerals, produits d'usines (Hollard), 429, Summary of Alloys (Jänecke), 429; Technical Methods of Ore Analysis (Low), 429; Blast Furnace Practice (Morgan), 429; The Elements of Metallography (Ruer), 430; Hints on Amalgamation and the General Care of Gold Mills (Adams), 575; Industries du plomb et du mercure. Bd. I. Métallurgie (Bouchonnet), 575; Die Metallhüttenchemie (Orthey), 576; Crystallography: An Elementary Manual for the Laboratory (Wadsworth), 576; Text-Book of Ore Dressing (Richards), 728; Fuel and Refractory Materials (Sexton), 728; The Chemistry of Cyanide Solutions Resulting from the Treatment of Ores (Clennell), 813; Die physikalisch-chemischen Eigenschaften der Legierungen (Dessau), 813; Analyse thermique et métallographie microscopique (Rengade), 814; The Corrosion of Iron and Steel (Sang), 814; Book of Precious Stones. Identification of Gems and Gem Minerals and Account of their Scientific, Commercial and Artistic Aspects (Wodiska), 814; Analyse der Silicat- und Carbonatgesteine (Hillebrand), 895; Industrie du chrome, du manganèse, du nickel et du cobalt (Ouvrard), 895; La soudure autogène des métaux (Ragno), 895; Analyse thermique et métallographie microscopique (Rengade), 896; Zur chemisch-mineralogischen Erforschung der Deutschen Kalisalzlagerstätten (Rinne), 896; Leitfaden der Mineralogie (Ruska), 896; Metallography (Desch), 1008; Treatise on Ore and Stone Mining (Foster), 1009; Kurze Uebersicht über sämtliche Legierungen (Jänecke), 1009; Metallography Applied to Siderurgic Products (Savoia), 1010; Hüttenmännische Probierkunde (Schütz), 1010; Mitteilungen aus dem eisenhüttenmännischen Institut der Kgl. Techn. Hochschule Aachen (Wüst), 1010; Dictionary of Portuguese Mining Terms, with French, English, and German Equivalents (Ackermann), 1110; The Corrosion and Preservation of Iron and Steel (Cushman, Gardner), 1110; Ore Deposits of South Africa (Johnson), 1111; Manual of the Chemical Analysis of Rocks (Washington), 1112; Bleiraffination durch Elektrolyse (Betts), 1363; Die Metallfärbung (Buchner), 1363; Lead Smelting (Collis), 1363; A Reconnaissance of the Gypsum

Deposits of California (Fess, Steyer), 1363; Die synthetischen Edelsteine (Grossmann, Neuburger), 1363; The Mercury Minerals from Terlingua, Texas (Hillebrand, Schaller), 1364; Handbuch der Mineralogie (Hintze), 1364; Durchführung des Roheisen-Erz Prozesses im Martinofen (Kahnert), 1364, Handb. der autogenen Schweissung (Kautny), 1364; Beiträge zur Ezaufbereitung (Lukaszczyk), 1364, Modern Foundry Practice (Sharp), 1365; Modern Assaying (Smith), 1365, Taschenbuch für Eisenhüttenleute, 1366, Beiträge zur Oxydation des Phosphors im basischen Konverter (Voigt), 1366; La néo-métallurgie, ses moyens et ses methodes (Benolt), 1537; Neue massanalytische Methoden zur Bestimmung von Eisen und Blei (Bollenbach), 1537, Etude sur la corrosion des métaux (Buzenac), 1537; Essais des fers et des aciers par corrosion (Frémont), 1537; Iron-ore Resources of the World, 1537; Studien über die Zusammensetzung heliumführender Mineralien (Lange), 1538; Note sur la fabrication électrolytique de l'aluminium (Lodin), 1538; A Treatise on Electrometallurgy (McMillan), 1538; Précis de métallurgie (Pécheux), 1539, Ueber die binären Systeme des Natriummetasilicats mit Lithium-, Magnesium , Calcium-, Strontium-, und Bariummetasilicat (Wallace), 1540; Der praktische Hochofenbetrieb (Bender), 1698; Mineralogia descrittiva (Bombici), 1698; Mitteilungen aus dem Institut fur Metallographie und Probierkunde an der kgl. sächs. Bergakademie Freiberg (Friedrich), 1698; The Cupola Furnace (Kirk), 1699; Die Untersuchungsmethoden des Eisens und Stahls (Rüdisüle)............ . . 1699

Photography: Die Herstellung von Diapositiven (Hanneke), 249, Optisches Hilfsbuch für Photographierende (Harting), 249, Vergrössern und Kopieren auf Bromsilberpapier (Löscher), 250; Die photographische Praxis (Schmidt), 252, Photographie (Vogel), 253, Taschenbuch der Photographie Ein Leitfaden für Anfänger und Fortgeschrittene (Vogel), 253; Photographisches Reisehandbuch (Wentzel, Paech), 253; Ueber Farbenphotographie und verwandte naturwissenschaftliche Fragen (Wiener), 254; Photography in Principle and Practice (Bottomley), 428, The American Annual of Photography (Tennant), 430; Wie erlangt man brillante Negative und schöne Abdrucke (Hauberrisser), 727; Traité pratique de photographie des couleurs (Niewenglowski), 895, Le diamidophenol acide en photographie (Underberg), 896, Lexikon für Photographie u Reproduktionstechnik (Emmerich), 1008, Kaufmännisches Handbuch des Photographen (Frank), 1363, Chemistry for Photographers (Townsend). 1699

Agricultural: Fabrikation des engrais chimiques (Fritsch), 249; Fertilizers and Manures (Hall), 249; Das Kalisilicat (Phonolithmehl) als Kalidüngemittel (Wein), 253, Mineralische Düngemittel u Ernteergebnisse (Schneider), 430, Kleines Handwörterbuch der Agrikulturchemie (Passon), 728; Kleines Handwörterbuch der Agrikulturchemie (Passon), 895; Soil Fertility and Permanent Agriculture (Hopkins), 1111, Die Kalk- und Magnesiadungung (Meyer), 1111; Fertilizers and Feeding Stuffs (Dyer), 1363, Chemie und landwirtschaftl Nebengewerbe (Meyer), 1365, Soils and Manures (Murray), 1365; Die Kalidüngung (Schneidewind), 1365; Düngerlehre (Stutzer), 1366, Agricultural Bacteriology, Theoretical and Practical (Percival), 1539; Fertilizers for Wheat Soils (Whitney) 1540

Fermentation Die Mikroörganismen der Gärungsindustrie (Jörgensen), 250; Leitfaden der Chemie für Brauer und Mälzer (Knorr), 250; Die Spiritusindustrie, ihre Technik, Steuern und Monopole (Linschmann), 250, Composition chimique des alcools d'industrie et des spiritueux (Moraucé), 251, Zuckerungstabellen zur gesetzlich erlaubten Verbesserung der Traubensäfte, und Weine, sowie der Obst- und Beerensäfte (Schätzlein), 430, Tabellen zur Ermittelung der freien Saüre, sowie der flüchtigen und nichtflüchtigen Saüren im Wein (Friese), 575; Praktische Destillateur-Kursus (Goettler), 576, Tafel zur Umrechnung der Volumprozente in Gewichtsprozente und der Gewichtsprozente in Volumprozente bei Branntweinen, berechnet nach den amtlichen Zahlen der kaiserlichen Normal-Eichungskommission (Plato), 576; La chimie et la bactèriologie du brasseur Hannut. (Flamand), 727; Bierbrauerei (Codounsky), 1008; Contribution a l'analyse physico-chimique des vins (Duboux), 1008; Die Malz- und Bierbereitung (Leyser), 1009; Praktische Mälzerei-und Brauerei-Betriebskoturolle (Schifferers), 1010; Distillazione del vino ed utilizzazione dei residui della vinificazione (Cettolini), 1110; Dal mosto al vino La fermentazione alcoolica, 1110; Illustriertes Brauerei-Lexikon (Delbruck), 1537; Atlas der mikroskopischen Grundlagen der Gärungskunde (Lindner), 1538; Utilisation des sous-produits de la vigne et du vin (Vermorel, Dantony) . 1699

Essential Oils Ueber die Entwickelung der Industrie der aetherischen Ole in den letzten 25 Jahren (Hesse), 428; Die moderne Parfümerie (Mann), 728, Laboratoriumsbuch für die Industrie der Riechstoffe (Simon), 728; Die ätherischen Oele Monographien über chemisch-technische Fabrikationsmethoden (Leimbach), 1364; Theorie der Gewinnung und Trennung der ätherischen Oele durch Destillation (Rechenberg).......... 1539

Acids, Alkalies and Salts: Die Fixierung des Luftstickstoffs und ihre Bedeutung für Ackerbau und Industrie (Erdmann), 248; Ueber die Darstellung des Chlorkaliums aus Hartsalz (Felb), 248; La fabrication électrochimique de l'acide nitrique et des composés nitrés à l'aide des éléments de l'air (Escard), 428; Fertilizer and Acid Plants (MacKnight), 429; Ueber die

Darstellung des Chlorkaliums aus Hartsalz (Feit), 575; The Manufacture of Sulphuric Acid and Alkali, with the Collateral Branches (Lunge), 576; Die Stickoxybildung aus Luft mit Hilfe einer Gleichstromentladung niedriger Spannung unter vermindertem Druck (Morden), 728; Ueber Luftsalpeter (Jurisch), 813; Die Gewinnung des Broms in der Kaliindustrie (Mitreiter), 814; Industries des acides minéraux. Acides sulfurique, chlorhydrique et azotique (Band), 894; La soude électrolytique (Brochet), 1363; Gesetz über Absatz von Kalisalzen vom 23 Mai 1910 (Silberberg), 1699; Illustr. Jahrbuch der Wirtschaft und Technik im deutschen Kalisalzbergbau, nebst Richskaligesetz mit einer krit. Einleitung (Stange).......... 1699

Glass and Ceramics: Glasätzerei (Miller), 251; History of the Clay-working Industry in the United States (Ries), 252, Einfaches chemisches Praktikum für Keramiker, Glastechnike, Metalltechniker usw. (Berdel), 428; Keramik (Rudolph), 430; Steingutfabrikation (Heim), 813; Porzellan (Ricke), 814; Aus der Praxis eines Glashüttenfachmannes (Schippman), 814; Die Tonwarenerzeugung, mit besonderer Berücksichtgung der chemischen Grundlagen (Rudolf), 1010; Photokeramik (Fleck), 1111; Die Bayerische Spiegelglasindustrie (Berlin), 1363; Der elektrische Ofen im Dienste der keramischen Industrie (Brown), 1363; La technique de l'émaillerie moderne (Grunwald), 1364; Laboratoriumsbuch für die Tonindustrie (Bollenbach), 1537; La céramique française (Peyre), 1539; Das Porzellan (Rieke).......... 1699

Cement: Portland Cement (Davis), 248; Der Erhärtungsprozess der Kalkhaltigen hydraulischen Bindemittel (Michaelissen), 251; Hydraulischer Kalk und Portlandzement, ihre Rohstoffe, physikalischen und chemischen Eigenschaften (Zwick), 254; Der Eisenbetonbau (Haimovici), 576; Anleitung zum Entwerfen und zur Berechnung der Standfestigkeit von Fabrikschornsteinen aus Mauerwerk, Eisen und Eisenbeton, nebst den hierüber erlassen Bestimmungen und die rauchfreie Verbrennung bei Dampfkesseln (Jahr), 576; Cement in Sea Water (Poulsen), 576; Zement im Meerwasser (Poulien), 814; Cement and How to Use it (Radford), 1111; Laboratoriumsbuch für die Zementindustries (v. Arlt), 1362; Zentralblatt für Chemie und Analyse der hydraulischen Zemente.......... 1366

Fuels and Lighting: Torfkoks und Kraftgas (Jabs), 250; Die flüssigen Heizmaterialien und ihre Anwendung (Rossmässler), 252; Les combustions industrielles Le controle chimique de la combustion (Rousset, Henri, Chaplet), 252; Kokerei und Teerprodukte der Steinkohle (Spilker), 253; Commercial Peat; Its Uses and Possibilities (Gissing), 428; Coal Tar and Ammonia (Lunge), 576; Modern Coking Practice; Including the Analysis of Materials and Products (Byrom, Christopher), 727; Ueber Gasöle und Oelgas (Hempel), 727; Acetylene: The Principles of Its Generation and Use (Leeds, Butterfield), 727; Rechentafeln für Beleuchtungstechniker (Bertelsmann), 813; American Producer Gas Practice and Industrial Gas Engineering (Latta), 813; Vorlesungen über Brennstoffkunde (Aufhäuser), 894; Illumination and Photometry (Wickenden), 896; Einrichtung und Betrieb eines Gaswerkes (Schäfer), 1010; Theorie und Praxis des Generatorbetriebes (Waldeck), 1010; Das Generatorgas, seine Erzeugung und Verwendung (Kietaibi), 1111; Betriebsbuchfuhrung für Gaswerksbetriebe (Greineder), 1363; Die Oelfeuerung im Schmiedebetrieb und im der Metalwarenfabrikation (Pick), 1365; L'éclairage industriel (Berthier), 1537; Die Technik der Verbrennung und Energiegewinnung aus städtischen Abfallstoffen (Meyer), 1538; Ueber ökonomischen Kohlenverbrauch (Parma).......... 1359

Petroleum and Asphalt: Erdwachs, Paraffin, und Montanwachs, deren Darstellung und Verwendung (Gregorius), 428; Untersuchung der Mineralöle und Fette, sowie der ihnen verwandten Stoffe (Holde), 428; Solid Bitumens (Peckham), 576; Fabrication des huiles minérales et pyrogénées (Ehrsam), 813; Oil (Mitchell), 1538; Ueber Asphalt- und verwandte Industrien (Weil).......... 1540

Paper: Die wirtschaftliche Bedeutung der techn. Entwicklung in der Papierfabrikation (Schaefer), 252; Kurzes Lehrbuch der Chemie für Papiertechniker (Skark).......... 1365

Explosives: Die Sprengstoffe. Darstellg. u. Untersuchg. der Sprengstoffe u. Schiesspulver (Kedesdy), 250; Die Ammonsalpetersprengstoffe (Escales), 428; Die Sprengstoffe, ihrer Chemie und Technologie (Biedermann), 1110; Les explosifs militaires violents (Macar, Dalattre), 1364; Annual Report of His Majesty's Inspectors of Explosives, 1698; Chloratsprengstoffe (Escales).......... 1698

Dyes and Textils: The Practical Dry Cleaner, Scourer and Garment Dyer (Baird), 247; Les succédanés de la soie. Les soies artificielles (Chaplet, Rousset), 248; Der Indigo und seine Konkurrenten (Felsen), 248; Lehrbuch der Farbenfabrikation (Gentele), 249; Handbuch der Farbenfabrikation (Zerr, Rübencamp), 254; Die volkswirtschaftliche Bedeutung des künstlichen Indigos (Jenke), 576; Mikrophotographischer Atlas der industriellen Faserstoffe (Zetzsche), 576; A Manual of Dyeing (Knecht), 727; A Course in Dyeing for Garment Dyers (Prag), 728; La soie artificielle et sa fabrication (Foltzer), 895; Ramie China Grass (Carter), 1008; Die Theorie des Färbeprozesses (Pelet-Jolivet), 1010; Chemische Technologie der Gespinstfasern, ihre Geschichte, Gewinnung, Verarbeitung und Veredlung (Witt, Lehmann),

1010; Dyeing and Cleaning (Farrell), 1111; Das Färben und Bleichen von Baumwolle, Seide, Leinen, Etc. (Herzfeld), 1111; Der Farberlehrling im Chemie Examen (Kielmeyer), 1364; Moderne Batistfarben (Zimmermann), 1366; Anleitung zur Unterscheidung von Textilmaterialen (Hünlich), 1537; Guide pratique de teinture moderne, suivi de l'art du teinturier dégraisseur (Thomas), 1540; Les succédanés de la soie (Chaplet, Rousset), 1698; Die Chemie der Cellulose, unter besonderer Berücksichtigung der Textil- u. Zellstoffindustrien (Schwalbe).... 1699

Paints and Varnish: Oelfarbe und Oelfarbenanstriche (Hebing), 249; Couleurs, peintures et vernis (Desalme, Pierron), 895; Linseed Oil and Other Seed Oils (Ennis), 895; An Introduction to the Chemistry of Paints, with Diagrams (Friend), 1537; Handbuch der Lach- und Firnis-Industrie (Seeligman, Tieke) 1539

Rubber: Manuel pratique de la fabrication du caoutchouc et du produits qui en dérivent (Heil, Esch), 249; Analyse du caoutchouc et de la guttapercha (Pontio), 252; Le caoutchouc (Fayol), 428; The Chemistry of India Rubber (Weber), 896, India Rubber and Gutta-Percha (McIntosh), 1009; Etude sur la production dû caoutchouc dans les colonies Françaises (Chartier), 1110; Le caoutchouc (Tillier).... 1540

Fats, Fatty Oils and Soaps: Die kaustische und kohlensaure Verseifung in der modernen Seifenindustrie. Die Haushaltungsseife (Kirchner), 813; Die Fette und Oele, Darstellung der Gewinnung und der Eigenschaften aller Fette, Oele u. Wachsarten, der Fett u Oelraffinerie u. der Kerzenfabrikation (Thalmann), 896; Einheitsmethoden zur Untersuchung von Fetten, Oelen, Seifen und Glycerinen sowie sonstigen materialien der Seifenindustrie, 1363, Technologie der Fette und Oele (Hefter), 1364; Beitrage zur Chemie u. Analyse der Fette (Heiduschka, Pfizenmaier).... 1537

Sugar: Manuel de la fabrication du sucre de betterave a l'usage des praticiens (Vrancken, Aulard, 253; The Manufacture of Cane Sugar (Jones, School), 429; Beet-Sugar Making and Its Chemical Control (Nikaido), 576; Der Zuckerrübenbau und die Fabrikation des Rübenzuckers, nach den neuesten Erfahrungen der Wissenschaft und der Praxis (Stift, Gredinger), 896; Technical Calculations for Sugar Works (Mittelstaedt), 1111; Ueber massanalytische Methoden zur Bestimmung der Zuckerarten (Lehmann), 1538, Jahresbericht über die Untersuchungen und Fortschritte auf dem Gesamtgebiete der Zuckerfabrikation, 1699; Ueber das Vorkommen von Raffinose in Rohzucker und deren Bestimmung (Strohmer) .. 1699

Leather: The Manufacture of Leather (Bennett), 247, Zur Kenntnis des Gerbprozesses (Schroeder), 576; Lederfabrikation (Krönlein), 813; Die pflanzlichen Gerbstoffe Uebersicht über Vorkommen, Eigenschaften, Gewinnung und Anwendung der wichtigeren pflanzlichen Gerbstoffe (Franke), 895; Practical Tanning (Fleming), 1111; Chemie der Gerbstoffe (Nierenstein).. 1538

TOWNSEND, J. S. The Theory and Ionization of Gases by Collision (book) 1540
Transference experiments with thallous sulphate and lead nitrate 1555
Transference measurements in sodium hydrogen sulphate solutions..................... 1151
Transference numbers, theory of the determination of, by the method of moving boundaries .. 862
TRAUBE, M. See Mengarini.
TREADWELL, F. P. Quantitative Analysis (book)....................................... 1112
TRIER, G. See Winterstein, E.
1,2,5-Trimethylcyclopentanol-1... 1065
Trimethyl-p-nitrophenylethylammonium iodide.. 770
Trinitrophenyl ether... 1292
TRNKA, R. Die physikalischen Eigenschaften des Bodens (book).......................... 576
TRÖGELE, F. Ueber das Verhalten der Alkaloide in den Organen der Atropa belladonna L. (book) 1540
TROY, H. C. See Publow, C. A.
TSCHIRCH, A. Handbuch der Pharmakognosie (book).................................... 1010
Tungstates, note on the paper entitled "Some Organic Tungstates"....................... 541
TURRENTINE, J. W. On the oxalates of hydrazine...................................... 579
TUTTON, A. G. H. Crystalline Structure and Chemical Constitution (book)................. 576

UHLENHUTH, P. and WEIDANZ, O. Praktische Anleitung zur Ausführung des biologischen Eiweissdifferenzierungsverfahrens mit besonderer Berücksichtigung der forensischen Blut-Fleischuntersuchung sowie der Gewinnung präzipitierender Sera (book).................. 253
UHLENHUTH, X. Untersuchungen über "Antiformin," ein bakterienauflösendes Desinfektionsmittel (book)... 253
Ultramicroscopic observations, some colloid-chemical aspects of digestion with............. 680
UNDERBERG, G. Le diamidophenol acide en photographie (book)........................... 896
University of Illinois section.............................Pr. 4, 46, 57, 64, 85 126
URBAIN, G. See Clarke, F. W.
Uric acid, elimination of, following copious water drinking between meals............... 1686

Valence, electron conception of, 1637; partial.. 1650
Vanadium, atomic weight...260, 1114, 1603

Vandevelde, A. J. J. Eléments de chimie générale; préparatoires a l'études biochimique des fermentations (book)........ 430

Van Haagen, W. K. Halides of tantalum........ 729

Vapor densities, apparatus for measurement of, of easily volatil substances........ 1624

Vapor pressure, determining molecular weights of solutes by lowering of, 1615; dynamic method for measuring, with application to benzene and ammonium chloride, 1448; identity of, as determined by the static and by the dynamic methods, 1623, of a pure substance, 471; of calomel, 1546; redetermination of the vapor pressures of mercury from 250° to 435°, 1434; static method for determining the vapor pressures of solids and liquids, 1412; studies in........897, 907, 1434, 1448 1541

Vapors, of organic compounds, action of magnesium upon........ 388

Vases, composition of some Greek........ 2591

Vermorel, V. and Dantony, E Utilisation des sous-produits de la vigne et du vin (book).... 1699

Vinson, A. E. The stimulation of premature ripening by chemical means........ 208

Vogel, E. Taschenbuch der Photographie. Ein Leitfaden für Anfänger und Fortgeschrittene (book)........ 253

Vogel, H. W. Photographie (book)........ 253

Voigt, M. Beiträge zur Oxydation des Phosphors im basischen Konverter (book)........ 1366

Volatilization of sulphuric acid when precipitates are heated........ 597

Volatil substances, apparatus for measurement of vapor densities of........ 1624

Vorbrodt, J. See Bruner, L

Vortmann, G. Uebungsbeispiele aus der quant. chem. Analyse (book)........ 1366

Vrancken, E and Aulard, A. Manuel de la fabrication du sucre de betterave a l'usage des praticiens (book)........ 253

Wadleck. Theorie und Praxis des Generatorbetriebes (book)........ 1010

Wadsworth, M. E. Crystallography· An Elementary Manual for the Laboratory (book)...... 576

Waidner, C W. and Burgess, G. K. Platinum Resistance Thermometry at High Temperatures (book)........ 1112

Walden. Die Lösungstheorien in ihrer geschichtlichen Aufeinanderfolge (book)........ 1700

Waldheim, M v Nach Autoren und Sachnamen geordnete Sammlung der wichtigsten Reagenzien und Reaktionen für Chemie, Pharmazie, Physiologie usw. 3 (book)........ 1366

Wallace, R C. Ueber die binären Systeme des Natriummetasilicats mit Lithium-, Magnesium-, Calcium-, Strontium-, und Bariummetasilicat (book)........ 1540

Wallach, O Tabellen zur chemischen Analyse (book)........ 1366

Ware, F C. See Renshaw, R R

Warren, W. H An apparatus for absolute alcohol........ 698

Washburn, E. W. A simple system of thermodynamic chemistry based on a modification of the method of Carnot, 467, 1636, the fundamental law for a general theory of solutions.653, 1636

Washington section........Pr 8, 47, 60, 67, 82, 68, 124, 130

Washington, H. Manual of the Chemical Analysis of Rocks (book)........ 1112

Water, composition of sea, near Beaufort, N C, 646; determination of ammonia nitrogen in, in the presence of hydrogen sulphide, 1256; destruction of invertase by, 985, determination of nitrates in, 630; ionization of, at 100 and 156°, 168; ionization of, at 218 and 306°, 172; ionization of, at high temperatures, 159; surface energy of........ 1169

Water drinking, studies on (uric acid elimination following copious water-drinking between meals)........ 1686

Watermelon seed, chemical examination of........ 360

Waters, C. E. A convenient potash bulb (note)........ 1691

Weber, C. O. The Chemistry of India Rubber (book)........ 896

Wedekind, E. and Lewis, J Neue Atomgewicht-Kurven (book)...... 814

Weidanz, O. See Uhlenhuth, P

Weight, concerning the correction of the apparent weight of a salt to the vacuum standard.... 507

Weil, S. F. Ueber Asphalt- und verwandte Industrien (book)........ 1540

Xylenes, heats of combustion of the.... 268, 293

1,3,4-Xylidylcamphoformenaminecarboxylic acid, 1503, 1512; xylidine salt.... 1503, 1511

Yttrium, basic nitrate of.... 873

Zerr, G. und Rübencamp, R. Handbuch der Farbenfabrikation (book).... 254, 1700

Zetzsche. Mikrophotographischer Atlas der industriellen Faserstoffe (book).... 576

Zimmermann, W. Moderne Batistfarben (book).... 1366

Zinc, electrolytic determination of, 530, 533, 1632; heat of solution of.... 456

Zsigmondy, R. Colloids and the Ultramicroscope (book).... 254

Zwick, H. Hydraulischer Kalk und Portlandzement, ihre Rohstoffe, physikalischen und chemischen Eigenschaften (book).... 254

PROCEEDINGS

OF THE

American Chemical Society

FOR THE YEAR 1910

EASTON, PA.:
ESCHENBACH PRINTING COMPANY
1910

PROCEEDINGS.

Contents.

January.

Council 1
Members Elected between November 15th and December 15th 1
Board of Directors 2

Meetings of the Sections:

Univ. of Missouri Section 3
Sodium Benzoate and the Referee Board, P. F. Trowbridge. The Detroit Meeting of the American Chemical Society, P. K. Francis. The Winnipeg Meeting of the British Association for the Advancement of Science, H. Schlundt. Factors which Influence the Digestibility of Feed, P. F. Trowbridge. Explosive Antimony, R. C. Palmer. Synthesis of Pyrimidine, R. B. Gibson.
Indiana Section 3
The Relation of Radioactivity to the Other Sciences, R. B. Moore. A Study of the Preparation and Preservation of Crushed Fruit and Fruit Syrups, I. L Miller. Some Analyses of Tomato Catsup, H. E. Bishop. (*a*) Temperance Beers. (*b*) Estimation of Dextrose, Dextrin and Maltose, H. E. Barnard.
Chicago Section 4
The Electric Theory of Oxidation and Reduction, J. Stieglitz.
University of Illinois Section 4
The Determination of Nitrogen by the Kober Method, F. W. Gill. (1) The Relation of the Water Supplies to the Typhoid Fever Death in Illinois. (2) A New Thermo-regulator for Incubators, E. Bartow.
Philadelphia Section 4
Legal Aspects of Chemistry—symposium. The Work of the Expert Witness, S. P. Sadtler. Textile Problems and Disputes, F. Dannerth. The Legal Side of Toxicology, M. Bearwood. The Enforcement of the Food and Drugs Act, C. S. Brinton. The Purification of Water by Ozone with Remarks on the Commercial Production of Distilled Water, H. Leffmann. The Jedun Vacuum Evaporator and its Application to By-products, A. P. Smith. Mondia Milk, A. E. Kitson
Louisiana Section 4
Manufacture of White Lead from Galena, Mr. McGee.
Section of Western New York 5
Estimation of Small Quantities of Arsenic, by Sanger's Modification of the Gutzeit Test, W. H. Watkins. The Action of Bacteria on Minerals, G. Morgan. Color in Preserved Fruits after Treatment with Lead Subacetate. New Sanitary Regulations in Raising and Shipping Oysters, W. L. Dubois. Microphotographs of Fine Points and Fibers, Mr. Morey. Errors in the Analyses of Linseed Oils, G. H. Pickard. Some Delicate Pycnometers and Glass Pens, R. E. Fowler. Vanadium in Chrome Iron Ore. Periodic Phenomena in the Aluminum Electrolytic Rectifier, R. Phillips.
Nebraska Section 5
Universities I Have Visited, C. S. Avery. The Reaction of the Blood, C.

F. Crowley. Studies in Asphalt, C. J. Frankforter. Some Notes on the Meeting of the British Association, F. J. Alway. Systematic Separation and Detection of the Common Acids, O. L. Barnebey.

Cornell Section 5
The Measurement of High Temperatures by Various Pyrometers, J. S. Shearer. Disposal of Sewage, H. N. Ogden.

Northeastern Section 6
The Bio-chemistry of Nucleic Acid, P. A. Levene. Alkali-insoluble Phenols, H. A. Torrey.

Kansas City Section 6
Benzoate of Soda Discussion, E. H. S. Bailey. Practical Advantages of Drying Alfalfa by Artificial Heat, R. E. Shuey.

Rhode Island Section 6
The Influence of Sodium and Potassium Salts upon the Subsequent Yield of Potato Tubers Planted under Like Manurial Conditions, H. J. Wheeler.

Milwaukee Section 7
High Temperatures and Other Measurements, O. Kowalke.

Georgia Section 7
Studies in the Sampling of Mixed Fertilizer, Size of Sample to be Taken, F. B. Porter. The Early History of the Cement Industry, C. N. Wiley. The Honey Locust as a Cattle Food, C. A. Wells. A Triumph of Chemistry Over Bacteriology in the Test of Polluted Waters, H. B. Arbuckle. An Investigation of the Stain of the Black Walnut on the Fish of Our Streams, G. P. Shingler.

Louisville Section 7
Fast Colors on Cotton, C. E. Martin.

Cincinnati Section 7
Some Experiments Illustrating Certain Phases of the Electrolytic Dissociation Theory, L. W. Jones.

Wisconsin Section 7
The Industrial Methods of Obtaining Resinous Products from the Southern Yellow Pine, L. F. Hawley.

Washington Section 8
Estimation of Glycerine in Meat Preparations, F. C. Cook. Enzymes and their Relation to Soil Fertility, M. X. Sullivan. Detection of Colocynth in Powdered Colocynth, V. K. Chesnut.

Lehigh Valley Section 8
The Relation of Economic Products and Geology in the Lehigh Valley, B. L. Miller. A Chemist's Slide Rule, R. K. Meade. Decomposition Temperature of Some Sulphates, W. S. Landis.

Cleveland Section 8
The Commercial Manufacture of Oxygen, C. F. Brush. The Brick Industry in Cleveland, F. K. Van Horn.

Minnesota Local Section 8
The Reaction between Ammonium Chloride and Potassium Dichromate when Heated, G. B. Frankforter, V. H. Roehrich and E. V. Manuel. The Nu-Cleation of Mixed Vapors in Dust-free Air, I. H. Derby and E. X. Anderson.

Deceased Members 8

February.

Minutes of the Forty-first General Meeting of the American Chemical Society... 9
Report of the Secretary for 1909. Report of the Editor of the Journal of the American Chemical Society and Chemical Abstracts. Report of the Journal of Industrial and Engineering Chemistry for the Year 1909. Treasurer's Report. Also reports of the Finance Committee of the American Chemical Society for the Year 1909, Librarian for the Year 1909. Division of Industrial Chemists and Chemical Engineers. Division of Physical and Inorganic Chemistry. Division of Fertilizer Chemistry. Division of Agricultural and Food Chemistry. Division of Organic Chemistry. Division of Pharmaceutical Chemistry. Section of Chemical Education. Section of Biological Chemistry. India Rubber Chemistry Section.
Council.. 30
Boston Meeting.. 30
Resolutions on the Death of Charles Benjamin Dudley.............. 32
Report of the Paper Committee of the American Chemical Society 32
Budget for 1910 38
Members Elected between Dec. 15, 1909 and Jan. 15, 1910.............. 40
Board of Directors 44
Meetings of the Sections:
Pittsburgh Section 44
Some Improved Gas Analysis Apparatus, E. J. Hoffman. The Determination of the Percentage of Phosphorus Retained with the Ferric Chloride in the Ether Separation, R. J. Wysor. The Analysis of Explosives, W. O. Snelling.
Section of Eastern New York 44
The Natural Resources of New Zealand, M. A. Hunter The Hydrate Theory of Solutions, A. T. Lincoln Recent Advances in the Liquefaction of Gases, C. F. Hale.
Wisconsin Section... 45
The Utilization of the Amino Acids and Polypeptids bv the Tubercle Bacillus, W. F. Koelker.
Indiana Section.. 45
Concerning the Decomposition of Uric Acid by Enzymes, C. E. May. Boiler Water in Railway Service, J. R. Francis. Scientific Treatment of the Problem of Cutting a Brilliant of Any Transparent Material, F. B. Wade. Morphine Determinations, A. D. Thorburn.
Iowa Section... 45
The Estimation of Cobalt and Arsenic in Smaltite, Nicholas Knight. Nitrogenous Excretion, S. Hartzell. Metalluric Tellurites, E. Wolesensky. Delicate Tests for Cobalt in the Presence of Nickel and Iron, W. J. Karslake. Colloidal Solutions, J. N. Pearce. Bleaching of Flour, E. W. Rockwood.
St. Louis Section.. 46
The Relation of Chemistry and Chemical Engineering to the Conservation of Our Natural Resources, H. E. Wiedemann. Timber Preservation, A. L. Kammerer, E. K. Fulks.
Louisiana Section.. 46
Waste Products, J. C. Mims.
New York Section... 46
Analyses of Some Antique Bronzes, M. Loeb and L. R. Morey. The Action of Radium Salts upon Ruby, C. Baskerville. Apparatus for Drying Flasks,

C. Baskerville and Reston Stevenson. The Origin of the Chemical Elements, H. R. Russell. Chemical Examination of Watermelon Seed, and Chemical Examination of Pumpkin Seed, F. B. Power and A. H. Salway. Further Researches in the Quinazoline Field, C. G. Amend and M. T. Bogert.
University of Illinois Section.. 46
The Heat of Solutions of Metals in Acids, L. L. Burgess. The Effect of External Conditions upon the Physiological Activities of Some De-nitrifying Organisms, J. H. Petit.
Syracuse Section.. 47
Invertase, C. S. Hudson. Some New Electro-chemical Processes, E. H. Archibald. An Electric Gas Meter, E. C. Scott. Report of the Recent Convention of Chemical Engineers, W. M. Booth. The Electrical Theory of Oxidation and Reduction, J. Stieglitz.
Cincinnati Section.. 47
Chemical Theories, J. Ellms.
Washington Section.. 47
Nitrification in Soils, K. F. Kellerman, E. R. Allen and I. G. McBeth. Availability of Iodophenin in the Separation of Acetanilid and Acetphenetidin, W. O. Emery. Translocation of Plant Food during Germination of Wheat, J. F. Breazeale.
Deceased Members.. 47

March.

Council.. 51
Members Elected between January 15th and February 15th.
Meetings of the Sections:
Puget Sound Section.. 56
Some Non-Ionic Reactions, W. M. Dehn. The Status of Powdered Coal as a Fuel, D. C. Farnham.
Chicago Section.. 56
The Council on Pharmacy and Chemistry and the Chemical Laboratory of the American Medical Association. W. A. Puckner. The Electrolytic Theory of Corrosion and an Amendment Thereto, W. D. Richardson.
North Carolina Section.. 56
Chemistry of Commercial Feeds, G. M. MacNider. The Determination of Flax Seed Products by the Specific Gravity Method, C. H. Herty and E. J. Newell. Caffiene in Our Beverages, E. V Howell. A Comparison of the Foster, the Tagliabue and the New York Board of Health Oil Testers, M. Orr. Application of Physical Chemistry to the Study of the Oleo-Resins, C. H. Herty. Bromination of Anthranilic Acid, A. S. Wheeler and W. M. Oates. Nature of Attractive Forces, J. E. Mills. The Delicacy of the Diphenylamine Test for Nitrates and Nitrites, W. A. Withers and B. J. Ray.
Cornell Section.. 57
Further Contributions to the Chemistry of the Phenolsulphonic Acid Method for Nitrates, D. S. Pratt. Ammonolysis of Hydrazine Sulphate, T. W. B. Welsh. Electrolytic Corrosion of Some Metals, G. R. White. The Influence of the Basicity of the Soil and of the Growth of Legumes on the Availability of Soil Nitrogen, T. L. Lyon. Report of the Boston Meeting, A., W. Browne.

Kansas City Section ... 57
Food Law and the Jobber, R. Hirsch. Food Law and the State, H. L. Jackson.
University of Illinois Section ... 57
Atomic Weight of Phosphorus, G. Jones. Adiabatic Determination of Heat of Combustion, R. H. Jesse, Jr. The Atomic Weight of Tantalum, C. W. Balke. A Measure of Thermodynamic Positivity and Negativity, C. G. Derick.
Pittsburg Section ... 57
The Manufacture and Analysis of Smokeless Powder, C. G. Storm. Results of Laboratory and Field Inspection of Various Painting Tests, H. A. Gardner.
Philadelphia Section ... 58
The Cause of Color in Plants, H. Kraemer. The Extraction of Gold from Sea Water, A. W. Comey. Is there Caramelization in Riva's Test, D. W. Horn. The Application of the Jet in Chemical Processes, O. Nagel. The Chemistry of the Tariff of 1909, C. C. Roberts.
Rhode Island Section ... 58
The Structure of Retene and its Relation to Some Natural Resins, J. E. Bucher.
Louisiana Section ... 58
The Causes of Variations in Sugar House Results, L. A. Becnel.
Northeastern Section ... 59
Color Photography at the Present Time, L. Derr.
University of Missouri Section ... 59
Glycogen Content of Beef Flesh, C. K. Francis. Apparatus for Measuring the Comparative Hardness of Fat or Similar Substances, E. A. Perkins.
Milwaukee Section ... 59
Iron and Steel, R. S. MacPherran Lead Smelting, B. L. Salomon.
California Section ... 59
The Bearing of Recent Work in Radioactivity on the Atomic Theory, E. C. Franklin.
Louisville Section ... 59
Reducing Oils for Paints, R. C. Lord. The Detection of Alumina in Water, W. H. Lovejoy. The Purchase of Coal on the B. T. U. Basis, A. M. Breckler. Gravimetric Determination of Reducing Sugars, F. F. Hasbrouck.
Cincinnati Section ... 60
The Interpretation and Value of Physical and Chemical Tests in the Control of Water Purification Plants, C. Bahlmann. The Biological Features of Water Purification at Cincinnati, Ohio, L. G. Gedesche.
Washington Section ... 60
Solubility of Gold in Nitric Acid, F. P. Dewey. The Detection of the Deterioration of Corn with Special Reference to Pellagra, C. L. Alsberg and O. F. Black.
Wisconsin Section ... 60
The Separation of Curd from Butter Milk, J. L. Sammis. The Importance of Metabolic Water in the Development of Living Organisms, S. M. Babcock.
New York Section ... 60
Nucleic Acids, P. A. Levene. Determination of Sodium Chloride in Milk, P. Poetschke. Some Colloid-chemical Aspects of Digestion, with Ultra-

microscopic Observations, J. Alexander. The Fate of Amino Acids in the Organism, G. Lusk.
Syracuse Section........ 60
The Chemist and the Community, A. D. Little. The Conference of the Sections, H. C. Cooper. The Chemist's Place in Industry, A. D. Little.
Section of Eastern New York........ 61
Modern Bacterial Methods of Sewage Treatment, L. P. Kinnicutt.
Minnesota Local Section........ 61
Deceased Members........ 61
San Francisco Meeting........ 62

April.

Council........ 63
Members Elected between February 15th and March 15th.

Meetings of Sections:

University of Illinois Section........ 64
Application of the Rare Earths to Incandescent Lighting, H. S. Miner. The Atomic Weight of Tantalum, C. W. Balke. A Measure of Thermodynamic Negativity and Positivity, C. G. Derick. Equilibrium between Amalgam and Amalgam Solutions, G. McP. Smith. The Alkylation of Cyanacetic Ether, J. C. Hessler. Opalescence and the Function of Boron in the Glaze, R. T. Stull.
Indiana Section........ 64
A Simple Method for Determining the Relative Strength of Acids and the Relative Strength of Bases, W. M. Blanchard. Some Problems in Iron Analyses, H. A. Schwartz. The Rare Earths and their Use in Incandescent Gas Mantles, H. S. Miner. Laboratory Notes, H. A. Duden. Laboratory Kinks, R. P. Noble.
Puget Sound Section........ 65
Mineralization of Some American Waters, R. B. Dole.
St. Louis Section........ 65
The Action of Magnesium upon the Vapors of Organic Compounds, E. H. Keiser. The Extraction of Glycerine from Soap Lye, C. B. Cluff.
Louisiana Section........ 65
Personal Experiences in South African Gold and Diamond Mines. T. L. Carter. Chemical Examination of Imported Merchandise, W. L. Howell. Some Notes on the Assay of Tincture of Nux Vomica, G. B. Taylor.
Kansas City Section........ 66
The History of the Development of the Elements, F. B. Dains. The Chemical Control of a Soap and Glycerine Factory, M. Brayton Graff.
Cornell Section........ 66
Problems of the Gas Engineer, C. F. Hirshfield. The Chemical Resources of the United States, J. E. Teeple.
Rhode Island Section........ 66
Field Notes from the Natural History of Silica, C. E. Swett. The Testing of Explosives for Use in Coal Mines with Special Reference to the Prevention of Mine Disasters. C. E. Munroe.
Chicago Section........ 67
Problems of the Linseed Oil Industry, O. Eisenschiml.
Northeastern Section........ 67
Present Conception as to the Constitution of Matter, D. F. Comstock. Production of Incandescent Mantles and Chemicals, M. C. Whitaker.

Washington Section.... 67
The Construction and Equipment of a Chemical Laboratory, W. D. Bigelow.
Syracuse Section.... 67
The Manufacture and Testing of Refractory Material, A. V. Bleininger.
Section of Eastern New York 67
Wireless Telegraphy and Telephony, W. J. Williams.
New York Section.... 67
The Determination of Copper in Blister and Refined Copper, W. C. Ferguson. Scrubbing Device for Vacuum System in the Laboratory, C. Baskerville. Rack for Holding Reagents in Bulk, J. L. Sporer. An Improved Ethylene Generator, V. L. King. A Constant Temperature Drying Oven and Gas Regulator, H. T. Beans. An Automatic Pipette, S. H. Beard. Description of a Modified Pettersson and Palmquist Apparatus, C. T. G. Rogers. Tests of Iron Wire for Standardization Purposes, C. H. Stone and C. E. Cheeseman.
California Section.... 68
The Electrical Precipitation of Suspended Matter, F. G. Cottrell.
Cincinnati Section.... 68
A Journey through the Navajo and Mogui Indian Countries, J. U. Lloyd.
Philadelphia Section.... 68
The Evidence Obtained during the Past Twelve Years for the Solvate Theory of Solutions, H. C. Jones.
Minnesota Section.... 68
The Chemical Replacement of the Metals by Each Other, L. Kahlenberg.
Deceased Members.... 69
Eighth International Congress o Applied Chemistry.... 75
Gmelin-Kraut's Handbook.... 76

May.

Council.... 77
Members Elected between March 15th and April 15th

Meetings of the Sections

Indiana Section 79
Glass Sands and Ball Clays of Florida, H H. Buckman. On the Purpose and Methods of the Chemistry Course in the Public School, F B. Wade. The Teaching of Chemistry in the University, J. H. Ransom.
St. Louis Section.... 79
Chemistry in America and Germany. Electrolytic Preparation of Hydrazine, R. F. Weber. Terpineless Extract of Lemon and Analysis Thereof, S. H. Baer. A Rapid Method of Estimating Iron in Iron Ores, L. McMaster. Ozone in Water Treatment, W. F. Monfort.
Chicago Section.... 80
The Chemist in a Brass Foundry, W. M. Corse The Borax Industry, the Mining and Manufacture of Borax and its Uses. The Development of the Borax Industry in California and Nevada, and Sources of Supply in Other Countries, S. T. Mather. Mining and Refining of Borax, F. M. Dupont. The Use of Borax in Manufacturing Enameled Sanitary Ware, C J. Wolff. The Use of Borax in Manufacturing Enameled Kitchen Ware, H. Coonley.
Nebraska Section.... 80
Present Status of the Bleached Flour Controversy, F J. Alway. Analysis of Soaps, S. H. Ross. Nitrogen Problems and Dry Farming, R. S. Trumbull. Determination of Humus, E. K. Files.

Louisville Section.. 80
Antitoxins, L. A. Brown. Liquid Mixtures of Constant Boiling Point, G. Ryland. Possible Variation in the Composition of Distiller's Dried Grains, A. M. Peter. Operation of the Louisville Filter Plant, W. H. Lovejoy. Bacteriological Examination of Water, F. M. Scales.
Milwaukee Section.. 81
The Methods of Production and Properties of the Chemical Dry Colors, C. H. Hall.
Rhode Island Section 81
Some Problems of the Testing Laboratory, W. H. Kenerson.
New York Section.. 81
Notes on the Determination of Essential Oils, F. D. Dodge. General Outline of the Leather Industry, A. Rogers. The Process of Bating, A. A. Claflin. Vegetable Tanning Materials, J. H. Yocum. Recent Advances in Chrome Tannage, O. P. Amend. The Coloring of Leather, F. E. Atteaux. Oils Used in the Leather Industry, E. A. Prosser.
Section of Eastern New York 81
Usefulness of Chemistry in Sanitation, H. W. Wiley.
Cincinnati Section 82
(*a*) Salt. (*b*) Yellow Fever, A. Springer.
Wisconsin Section.. 82
Some Chemical Problems of the Forest Products Laboratory, H. S. Bristol.
Washington Section 82

BOARD OF DIRECTORS.

The Directors of the American Chemical Society met at the Chemists' Club, New York City, at 3 P.M., Saturday, December 18th, with Messrs. Whitney, Bogert, Hallock, McMurtrie, Parker and Parsons present.

After careful consideration of the estimates by the various officers and the income of the Society, a budget was approved to be presented to the Council at the annual meeting. This budget as finally adopted will be found in the Proceedings of February, 1910.

It was voted that the subscription rate for the Society's publications be as follows:

Any one of the three publications	$ 6.00
Any two of the three publications	10.20
All three publications	12.60

with $16^2/_3\%$ discount to the trade, libraries and clubs of ten or more individuals, and a further discount of fifty cents per subscriber on the combined rates above stated to clubs of twenty-five or more furnished through any firm, corporation, association or individual.

It was voted that these subscription rates shall begin with the March issue of the Journals and that no subscriptions under the old rates shall be accepted to expire later than February 20, 1911.

The meeting then adjourned. CHARLES L. PARSONS, *Secretary.*

MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons, Durham, N. H.]

UNIVERSITY OF MISSOURI SECTION.

The first regular meeting was held on Friday evening, October 1st, at 7 o'clock, in the Chemistry Building. Dr. P. F. Trowbridge presented a paper on "Sodium Benzoate and the Referee Board."

The second regular meeting was held on Friday evening, October 15th, at 7 o'clock, in the Chemistry Building. Mr. P. K. Francis addressed the Section on "The Detroit Meeting of the American Chemical Society."

The third regular meeting was held on Friday evening, October 29th, at 7 o'clock, in the Chemistry Building. Dr. Hermann Schlundt presented a paper on "The Winnipeg Meeting of the British Association for the Advancement of Science."

The fourth regular meeting was held Friday evening, November 19th, at 7 o'clock, in the Chemistry Building. The paper of the evening was presented by Dr. P. F. Trowbridge on "Factors which Influence the Digestibility of Feed."

The fifth regular meeting was held Friday evening, December 3rd, at 7 o'clock. R. C. Palmer spoke on "Explosive Antimony." R. B. Gibson reviewed the "Synthesis of Pyrimidine."

C. ROBERT MOULTON, *Secretary.*

INDIANA SECTION.

The Section met October 8th at Shortridge High School, Indianapolis.

Annual reports from the officers were read. The following were elected for the ensuing year: *President*, R. B. Moore; *Vice-President*, P. N. Evans; *Secretary-Treasurer*, A. D. Thorburn; *Executive Committee*, John White, R. P. Noble, H. E. Bishop. President R. B. Moore addressed the Section on "The Relation of Radioactivity to the Other Sciences."

The Section met Friday evening, November 12th, in the office of the State Food and Drug Laboratory.

The following papers were presented:

"A Study of the Preparation and Preservation of Crushed Fruit and Fruit Syrups," by Ivy L. Miller. "Some Analyses of Tomato Catsup," by H. E. Bishop. (*a*) "Temperance Beers." (*b*) "Estimation of

Dextrose, Dextrin and Maltose," by H. E. Barnard. About 20 members were present.
A. D. THORBURN, *Secretary.*

CHICAGO SECTION.

The November meeting was held at Kent Chemical Laboratory, University of Chicago, on Friday evening, November 12th, at 8.00 o'clock.

The lecture of the evening was on "The Electric Theory of Oxidation and Reduction," by Prof. Julius Stieglitz, University of Chicago.

The University laboratory was open for inspection during the evening.

Seventy-eight attended dinner at 6.15 P.M. and 200 were present at the meeting which was perhaps the best the Chicago Section has ever held.

A. L. NEHLS, *Secretary.*

UNIVERSITY OF ILLINOIS SECTION.

The November meeting was held November 16th, at the Chemistry Building.

The following papers were presented: "The Determination of Nitrogen by the Kober Method," by F. W. Gill. (1) "The Relation of the Water Supplies to the Typhoid Fever Death Rate in Illinois." (2) "A New Thermo-regulator for Incubators," by Dr. E. Bartow.

L. H. SMITH, *Secretary.*

PHILADELPHIA SECTION.

The regular meeting of the Section was held at the Engineers' Club, Philadelphia, Thursday evening, November 18th, at 8 o'clock.

The following three Councilors were elected for 1910: G. E. Barton, D. W. Horn and W. T. Taggart.

The program was: Legal Aspects of Chemistry—symposium. "The Work of the Expert Witness," by Samuel P. Sadtler. "Textile Problems and Disputes," by Frederic Dannerth. "The Legal Side of Toxicology," by Matthew Beardwood. "The Enforcement of the Food and Drugs Act," by C. S. Brinton.

The usual informal dinner was served at 6.30 P.M.

The regular December meeting was held at the Engineers' Club, Philadelphia, Thursday evening, December 16th, at 8 o'clock.

After the usual dinner the following program was presented: "The Purification of Water by Ozone with Remarks on the Commercial Production of Distilled Water," by Henry Leffmann, illustrated by apparatus and lantern slides. "The Jedun Vacuum Evaporator and Its Application to By-products," by A. P. Smith, illustrated by lantern slides. "Mondia Milk," by A. E. Kitson.
F. E. DODGE, *Secretary.*

LOUISIANA SECTION.

The thirty-fifth regular meeting was held on Friday, November 19th, at 8 P.M., in the Directors' Room of the New Orleans Board of Trade. President F. C. Johnson presided and the attendance was very good.

The program for the evening consisted of a paper by Mr. W. J. McGee on the "Manufacture of White Lead from Galena." Mr. McGee spoke of a new process using the lead ore directly as a starting material and carried the process through its various chemical and financial aspects. Later he spoke of the adulteration of white lead with barytes. A general discussion followed the reading of the paper and a vote of thanks from the Society was tendered Mr. McGee. W. L. HOWELL, *Secretary.*

SECTION OF WESTERN NEW YORK.

The regular meeting was held November 19th, Vice-President Lidbury presiding.

The program was of a general nature, several members making reports on special subjects as follows: "Estimation of Small Quantities of Arsenic, by Sanger's Modification of the Gutzeit Test," by W. H. Watkins. "The Action of Bacteria on Minerals," by Geo. Morgan. "Color in Preserved Fruits after Treatment with Lead Subacetate," and "New Sanitary Regulations in Raising and Shipping Oysters," by W. L. Dubois. "Microphotographs of Fine Points and Fibers," by Mr. Morey. "Errors in the Analysis of Linseed Oils," by G. H. Pickard. "Some Delicate Pycnometers and Glass Pens," by R. E. Fowler. "Vanadium in Chrome Iron Ore," and "Periodic Phenomena in the Aluminum Electrolytic Rectifier," by Ross Phillips. N. W. SHED, *Secretary.*

NEBRASKA SECTION.

The fifty-seventh annual meeting of the Section was held in the Lecture Room of the Chemistry Laboratory of the University of Nebraska, Saturday, November 20th, at 8 P.M., with the following program: "Universities I Have Visited," by Chancellor S. Avery. "The Reaction of the Blood," by Dr. C. F. Crowley. "Studies in Asphalt," by Mr. C. J. Frankforter.

The fifty-eighth annual meeting of the Section was held in the Lecture Room of the Chemistry Laboratory of the University of Nebraska, Wednesday, December 15th, at 8 P.M.

The Section listened to addresses on "Some Notes on the Meeting of the British Association," by Dr. F. J. Alway, and on "Systematic Separation and Detection of the Common Acids," by Mr. O. L. Barnebey.

BENTON DALES, *Secretary.*

CORNELL SECTION.

The November meeting was held Tuesday evening, November 23rd, at 8 o'clock. In order that illustrative experiments might be shown, the Section met in Rockefeller Hall. The lecture was by Prof. J. S. Shearer on "The Measurement of High Temperatures by Various Pyrometers." L. M. Dennis was re-elected Councilor for the coming year. Light refreshments were served after the meeting.

The December meeting was held in Morse Hall, Wednesday, December 15th, at 8 P.M. Prof. H. N. Ogden presented the subject: "Disposal of Sewage." A light lunch followed the meeting.

H. W. GILLETT, *Secretary*.

NORTHEASTERN SECTION.

The ninety-fifth regular meeting of the Section was held Friday, November 26th, at 8 P.M., at the Twentieth Century Club, Boston.

Doctor P. A. Levene addressed the Section upon "The Bio-chemistry of Nucleic Acid."

Professor H. A. Torrey, of Harvard University, followed with an address upon "Alkali-insoluble Phenols."

The election of officers and members of the Council for 1910 results as follows: *President*, S. W. Wilder; *Vice-President*, Karl Langenbeck; *Secretary*, K. L. Mark; *Treasurer*, H. C. Lythgoe; *Executive Committee*, F. E. Gallagher, W. C. Bray, G. S. Forbes, G. R. Underwood, L. C. Newell; *Councilors*, L. P. Kinnicutt, G. N. Lewis, W. L. Jennings, H. J. Skinner Dinner was served at 6.30 P.M.

KENNETH L. MARK, *Secretary*.

KANSAS CITY SECTION.

The November meeting was held in Kansas City, Kansas, on Saturday evening, November 27th.

The program began at 5.30 P.M., with a paper by Professor E. H. S. Bailey on the "Benzoate of Soda Discussion."

After supper Mr. Ralph E. Shuey read a paper on the "Practical Advantages of Drying Alfalfa by Artificial Heat."

The December meeting was held at the Eldridge Hotel, Lawrence, Kansas, on Saturday evening, December 11th.

The Section met in the parlor of the Hotel at 5 o'clock. Officers for the coming year were announced: *President*, F. W. Bushong; *Vice-President*, M. Brayton Graff; *Secretary-Treasurer*, E. A. White; *Assistant Secretary*, D. F. McFarland; *Councilor*, E. H. S. Bailey.

After a fifteen-minute talk by the President- and Vice-President-elect dinner was served, followed by a lecture on "Some Rare Earth Separation Methods," by Professor Benton Dales, Univ. of Nebr.

E. A. WHITE, *Secretary*.

RHODE ISLAND SECTION.

The second meeting of the Section was held at the University Club, Thursday evening, December 2nd. Dinner was served promptly at 7 o'clock.

Dr. H. J. Wheeler, Director of the Rhode Island Argicultural Experiment Station, then presented the paper for the evening on "The Influence of Sodium and Potassium Salts upon the Subsequent Yield of Potato Tubers Planted under Like Manurial Conditions."

ALBERT W. CLAFLIN, *Secretary*.

MILWAUKEE SECTION.

The regular meeting of the Section was held Friday evening, December 3rd, at the Blatz Hotel. Dinner was served at 6.30 P.M. with 35 present. After a lecture on "High Temperatures and Other Measurements," by Mr. Otto Kowalke, Mr. W. V. Young, of the Hoskins Mfg. Co., of Detroit, gave a practical demonstration of pyrometers and electric furnaces.

H. M. SOPER, *Secretary.*

GEORGIA SECTION.

The December meeting was held at the State Capitol on December 4th, and the following program given:

"Studies in the Sampling of Mixed Fertilizers, Size of Sample to be Taken," by F. B. Porter. "The Early History of the Cement Industry," by C. N. Wiley. "The Honey Locust as a Cattle Food," by C. A. Wells. "A Triumph of Chemistry Over Bacteriology in the Test of Polluted Waters," by H. B. Arbuckle. "An Investigation of the Stain of the Black Walnut on the Fish of Our Streams," by G. P. Shingler.

The following officers were elected for the year 1910: *President,* R. E. Stallings; *Vice-President,* W. C. Dumas; *Secretary,* J. S. Brogdon; *Councilor,* W. P. Heath.

W. C. DUMAS, *Retiring Secretary.*

LOUISVILLE SECTION.

The December meeting was held in Room 700 of the Atherton Building on the 6th. The paper for the evening was given by C. E. Martin on "Fast Colors on Cotton."

F F. HASBROUCK, *Secretary.*

CINCINNATI SECTION.

The 154th regular meeting was held Wednesday, December 8th, at 8 P.M., in the Chemical Lecture Room of the University of Cincinnati. The topic of the evening, "Some Experiments Illustrating Certain Phases of the Electrolytic Dissociation Theory," was presented by Prof. Lauder W. Jones.

The following officers were elected for 1910: *President,* Joseph W. Ellms; *Vice-President,* Archibald Campbell, Otto Dieckmann; *Recording Secretary,* Alfred Smith; *Financial Secretary,* Max H. Goettsch; *Executive Committee,* B. M. Pilhashy, Clarence Bahlmann, Mortimer Bye; *Councilor,* Alfred Springer.

RALPH E. OESPER, *Retiring Secretary.*

WISCONSIN SECTION.

The annual meeting of the Section was held at Madison on Wednesday, December 8th, at 8 P.M., in Room 102 of the Chemistry Building.

The following address was given: "The Industrial Methods of Obtaining Resinous Products from the Southern Yellow Pine," by Dr. L. F. Hawley, Forest Service, U. S. Department of Agriculture.

FRANCIS C. KRAUSKOPF, *Secretary.*

WASHINGTON SECTION.

The 194th meeting was held Thursday, December 9th, at 8 P.M., in George Washington University.

The program was as follows: "Estimation of Glycerine in Meat Preparations," by F. C. Cook. "Enzymes and Their Relation to Soil Fertility," by M. X. Sullivan. "Detection of Colocynth Seed in Powdered Colocynth," by V. K. Chesnut.

W. B. D. Penniman was elected Councilor in place of E. T. Allen, resigned.

J. A. LECLERC, *Secretary.*

LEHIGH VALLEY SECTION.

The regular fall meeting of the Section was held at the Hotel Allen, Allentown, Friday, December 10th, at 8 P.M.

Election of officers resulted as follows: *Chairman,* J. T. Baker; *Secretary,* Geo. C. Beck; *Councilor,* Geo. P. Adamson.

The papers presented were: "The Relation of Economic Products and Geology in the Lehigh Valley," by B. L. Miller, Professor of Geology, Lehigh University. "A Chemist's Slide Rule," by R. K. Meade. "Decomposition Temperature of Some Sulphates," by W. S. Landis.

A number of members and guests met informally for dinner at 7 P.M.

GEO. C. BECK, *Secretary.*

CLEVELAND SECTION.

The first annual and tenth regular meeting was held in the Geology Department of Case School of Applied Science, December 13th, at 8 o'clock.

The following papers were presented: "The Commercial Manufacture of Oxygen," by Charles F. Brush. "The Brick Industry in Cleveland," by Professor F. R. Van Horn, illustrated with lantern slides.

NORMAN A. DUBOIS, *Secretary.*

MINNESOTA LOCAL SECTION.

The 22nd regular meeting was held Friday evening, December 17th, in the Chemical Laboratory, University of Minnesota.

The papers presented were: "The Reaction between Ammonium Chloride and Potassium Dichromate when Heated," by G. B. Frankforter, V. H. Roehrich and E. V. Manuel. "The Nucleation of Mixed Vapors in Dust-free Air," by I. H. Derby and E. X. Anderson.

FRANCIS C. FRARY, *Secretary.*

DECEASED MEMBERS.

Irving E. Beach, Lawrence, Mass.
Edward M. Davies, November 24th, Saltville, Va.
Irwin La Verne Powers, August 28th, Niagara Falls, N. Y.
Arthur McBride Ransom, Auburn, Ala.
Edward C. Smith, September 17th, Joliet, Ill.
Herbert H. Wing, Monticello, N. Y.
John A. Young, November 10th, San Francisco, Calif.

Issued with the February Number, 1910.

Proceedings.

MINUTES OF THE FORTY-FIRST GENERAL MEETING OF THE AMERICAN CHEMICAL SOCIETY.

The forty-first general meeting of the American Chemical Society was held in Boston, Mass. in affiliation with the American Association for the Advancement of Science, from Tuesday, December 28, to Friday, December 31, 1909.

The meeting opened with meetings of the Industrial, Organic and Physical and Inorganic Divisions and the Section of Chemical Education on Tuesday in the Lowell Building of the Massachusetts Institute of Technology. Dr. D. L. Randall acted as press secretary for *Science*.

The program and abstracts of the minutes of the various Divisions and Sections are given later in these pages.

On Tuesday afternoon excursions were enjoyed to chemical works and on Tuesday evening a "smoker" complimentary to the visiting chemists was given by the Northeastern Section at the Hotel Brunswick, where an extremely interesting program containing many humorous events was enjoyed.

On Wednesday the Society met in general meeting in the New Lecture Hall of Harvard University and the following addresses were presented in general session.

Methods Employed in Precise Chemical Investigations. T. W. Richards.

On the Constitution of Curcumine—the Coloring Matter of Turmeric. C. Loring Jackson and Latham Clarke.

The Application of Physical Chemistry to the Study of Oleoresins. Charles H. Herty.

The Function of Chemistry in College Education. Lyman C. Newell.

The Cause of Color in Organic Compounds. Richard S. Curtiss.

The United States Pharmacopoeia and the American Chemical Society. Joseph P. Remington.

The Past and Future of the Study of Solutions. Louis Kahlenberg, retiring Vice-President Section C, American Association for the Advancement of Science.

The Chemist's Place in Industry. A. D. Little.

In the evening President Whitney's address was delivered before the assembled chemists in the Lowell Building of the Massachusetts Institute of Technology and was upon the subject: "Some Chemistry of Artificial Light." The lecture was experimentally illustrated.

On Thursday morning a general business meeting of the Society was held in the Lowell Building at which the reports of the officers of the Society were received and read. The following miscellaneous business was then transacted.

It was reported to the members that a majority of the Council had approved the nomination of the Right Honorable John Wm. Strutt (Lord Rayleigh), Madame S. Curie, Professor J. D. van der Waals, Sir James Dewar, Professor R. Fittig and Professor J. W. Mallet for honorary membership in the Society and that all preliminaries required by the Constitution for their election had been met. On motion from the floor, each of the before-mentioned chemists was unanimously elected to honorary membership in the Society.

Dr. H. P. Talbot presented the same resolutions which were passed by the Council in memoriam of Charles Benjamin Dudley and these were unanimously adopted by the Society by rising vote. They will be found in full in the Proceedings of the Council.

Mr. S. T. Mather spoke for a few moments to the meeting in regard to the summer meeting in San Francisco and the many pleasures awaiting the members there and invited the Society to examine the borax mines of the Thorkildsen-Mather Co. at Lang, California, near which it was anticipated the train carrying the members might pass.

The attention of the Society was called to the Berthelot Memorial being erected to one of our deceased honorary members and the desirability that members of the Society should contribute thereto. It is hoped that further subscriptions of one or two dollars each may be received by the Secretary, which will be duly acknowledged.

The President then announced the election of Wilder D. Bancroft as President of the Society and Alexander Smith, A. D. Little, L. H. Baekeland and W. L. Dudley as Councilors-at-Large.

Following this announcement a unanimous vote of thanks was passed to the President and chemical faculty of the Massachusetts Institute of Technology and to the President and chemical faculty of Harvard College for the courtesies extended to the Society and for the use of their buildings and lecture halls; to A. D. Little, T. W. Richards, A. A. Noyes, W. H. Walker, C. R. Sanger, H. P. Talbot, J. F. Norris and H. A. Torrey, Chairman of the local committees, and to the members of those committees for their unceasing efforts in our behalf, and to Walter Baker Chocolate Co., New England Gas & Coke Co., Massachusetts Breweries Co., Wood Worsted Mills, Forbes Lithograph Mfg. Co., American Woolen Co., Champion International Co., Felton & Sons, Inc., Fore River Ship-Building Co. and the Massachusetts State Board of Health for the privileges accorded to our members to examine their various works and laboratories.

The business meeting then adjourned and the Society met in divisional and sectional meetings throughout Thursday and Friday in the Lowell Building.

On Thursday night at 7 o'clock the annual subscription dinner was held in the banquet hall of the Somerset Hotel and was very largely attended and thoroughly enjoyed by all.

On Friday afternoon excursions were participated in by the members to Lawrence, Mass., where the Wood Worsted Mills, the Water Supply and Sewage Experiment Station of the State Board of Health and the Water Filtration Plant were examined; to Fore River, where the Fore River Ship-Building Co. was visited, and to South Boston to visit the distilleries of Felton & Son, Inc.

The meeting was the largest ever held by the American Chemical Society and the continually increasing enthusiasm prevalent throughout the Society was everywhere manifest. 558 members and guests registered and a considerable number were present whose names were not secured. The number of guests approximated 30.

The papers read before the meeting will be found under the divisional heads which follow later.

Report of the Secretary for 1909.

The current year has been no exception to the continued progress of the American Chemical Society and there was never a time in its history when the chemists of the country were more thoroughly organized and in hearty accord and sympathy with the work which it is trying to do. The publications have been issued promptly throughout the year with the single exception of the December number of the *Journal of Industrial and Engineering Chemistry*, which was held up on account of difficulties with the Index. The policy of organizing the Society in Divisions, begun in 1908, has been continued during the year and the Divisions of Physical and Inorganic Chemistry, Fertilizer Chemistry, Agricultural and Food Chemistry, Organic Chemistry and Pharmaceutical Chemistry have been organized and their work is daily growing in importance. The Baltimore Meeting was the largest ever held in the history of the Society and the Detroit Summer Meeting, while smaller in numbers than the Winter, which is always the case, had the largest attendance of any meeting ever held by the Society in the summer time.

During the year the Society has passed the record of all other chemical societies in regard to the numbers of its membership and is now the largest chemical society in the world. The membership of the Society at the time of the Baltimore Meeting was 4004. It is now 4502, a net gain of approximately 500 members. The membership statistics are as follows:

Honorary members	12
Life members	13
Corporation members	17
Members	4460
Total	4502
Elected during 1909 but not yet qualified	62
Grand total	4564

During the year the Society has lost by death one of its honorary members, Julius Thomsen, of Copenhagen, Denmark, and the following members: Gilbert N. Batchelder, Manzanillo, Cuba; Irving E. Beach, Lawrence, Mass.; John D. Billings, Syracuse, N. Y.; Edward M. Davies, Saltville, Va.; H. Augustus Hunicke, St. Louis, Mo.; John P. Ihart, Liberty, N. Y.; William Lyon, Los Angeles, Calif.; John K. Mackenzie, Chicago, Ill.; S. E. Nelson, Devil's Slide, Utah; Irwin La V. Powers, Boston, Mass.; Arthur McB. Ransom, Auburn, Ala.; Edward C. Smith, Joliet, Ill.; C. E. Strunz, Pueblo, Colo.; A. Sydney Warren, Buffalo, N. Y.; A. F. Watson, Dublin, Ireland; W. F. Wheeler, Urbana, Ill.; Herbert H. Wing, Monticello, N. Y.; Theodore R. Wolf, Newark, Del.; Heman A. Wood, Fargo, N. D.; John A. Young, San Francisco, Calif.; C. Irving Zimmerman, Madison, Wis.

The number of members not in arrears registered in the Local Sections on December 1, 1908 was 2816, and on December 1, 1909 was 3237.

The numbers in each Section for 1908 will be found in the Proceedings of 1909, page 17. For 1909 they are as noted below.

During the year the Local Sections have, as heretofore, shown strong loyalty to the welfare of the whole Society and have fully met the spirit which pervades almost all of the Sections of due economy in their local expenses in order that the funds of the Society may be utilized to meet the great cost of our publications, as most of the members realize fully that the Society is expending a much larger proportion of its income upon its publications than any other unendowed society in the world. Every member secures the benefit of any sacrifice he may make in his Local Section by the increased good which results to the whole Society therefrom.

According to the change in the Constitution the accounts with the Local Sections were placed in the hands of the Secretary to whom their treasurers make report. The following is a summary of the sectional accounts for the year, showing the number of members in each, the balance of funds saved by them in 1908 and credited to their 1909 account and the amounts drawn from the Treasurer's office in 1909; also the expense per member in each Section.

American Chemical Society 1909 Account with

Local Section.	No. paid members.	Cr.	Dr.	Expense per member.
California	148	9.88	109.88	0.74
Chicago	250	122.19	172.19	0.69
Cincinnati	77	00.00	115.50	1.50
Cleveland	109	00.00	40.00	0.36
Columbus	45	49.80	49.80	1.10
Cornell	27	50.90	24.90	0.90
Eastern New York	50	00.00	50.00	1.00
Georgia	27	00.00	15.00	0.55

AMERICAN CHEMICAL SOCIETY 1909 ACCOUNT WITH

Local Section.	No. paid members.	Cr.	Dr.	Expense per member.
Indiana	58	13.25	73.25	1.26
Iowa	38	00.00	7.70	0.20
Lehigh Valley	41	0.63	25.63	0.62
Louisiana	27	00.00	25.00	0.93
Louisville	22	00.00	20.00	0.91
Kansas City	80	00.00	80 00	1.00
Michigan	107	73.25	73.25	0.68
Milwaukee	42	00.00	61.50	1.50
Minnesota	56	0.80	25.80	0.37
Nebraska	24	10.61	10.61	0.44
New York	666	00.00	100 00	0.15
North Carolina	26	00.00	30.00	1.15
Northeastern	382	13 03	313.03	0.82
Philadelphia	217	00.00	200 00	0 92
Pittsburg	145	42.57	142.57	0.98
Puget Sound	30	00.00	25.00	0 83
St. Louis	63	29.13	89.13	1.41
Syracuse	61	00.00	50.00	0.82
Washington	229	00.00	150.00	0 66
Western New York	65	00.00	97.50	1 50
Wisconsin	51	18.51	68.51	0.98
University of Illinois	54	14.81	39 81	0.74
University of Missouri	20	00 00	10.00	0.50
	3237	449.36	2295.56	0.61

It is worthy of note that in spite of the increased membership of the Local Sections during the year there has been a slight decrease in cost per member.

During the fiscal year, December 1, 1908, to December 1, 1909, the Secretary has made collections to the amount of $48,969.12, divided as follows:

Members' subscriptions	$41,763.50
Subscriptions from non-members	2,979 38
Sales of back numbers	3,100.84
Foreign postage	515.29
Reprints	369.90
Reinstatements	52.55
Exchange	11.93
Interest	175.73

This amount was duly transmitted to the Treasurer of the Society.

The special sale of back numbers, which was begun in 1908, was continued by vote of the Directors until April 1, 1909. The effect of this sale has been noteworthy, as a distinct interest was aroused throughout the country and throughout the world to fill up partial sets and partial volumes so that the back number account, the receipts of which were estimated at $500.00 for the year, really assumed the magnitude of $3,100.84. On the close of the sale several thousand copies of certain excessive issues of copies of the *Journal of the American Chemical Society* were destroyed, leaving the stock in much better condition than before, and by purchase of certain months that were nearing exhaustion the stock is still as a whole in excellent condition. The Journals which in the early part of the year were stored in a basement near the office of the Eschenbach Printing Company, have been removed to the new building erected by them without expense to the Society and are now in excellent condition.

The following is a summary of the back numbers sent out by the Secretary during the year together with the present stock of journals and the condition of the mailing lists.

Copies of the Society's publications sent out from December 1, 1908, to December 1, 1909, aside from the mailing lists	31,724
Copies of the Journals and Chemical Abstracts in stock	44,068
Copies of the General Index in stock	495
Copies of the Anniversary Number in stock	298
Mailing list for both Journals and Abstracts	4,187
Mailing list for Abstracts only	157
Mailing list for Journal only	412
Mailing list for Industrial Journal only	104

It is still desired to purchase certain back copies of the Journal and members will confer a favor upon the Secretary by looking through their stock and comparing it with the advertising pages of the *Journal of the American Chemical Society*, where a regular advertisement is run by the Secretary with offers for missing back numbers. Vols. 3, 4, 5, 17, 18, 20 and 22 have already been reduced below the limit set by the Council for their sale except in complete sets. The Society now has but three complete sets of its publications left for sale.

Perfect harmony exists throughout the whole Society and all of our members appear to be working together with decided enthusiasm for the upbuilding of American chemistry and the circulation of the results of American chemical research.

The Secretary wishes to take this opportunity to thank the members throughout the Society for the loyal support which they have given him in his efforts to increase our strength and usefulness throughout the country. Early in the year he sent a communication asking for their support in the attempt to bring up the membership of the Society to 4500 and the loyalty and enthusiasm with which they responded is shown by the fact that this number was not only reached but exceeded.

CHARLES L. PARSONS,
Secretary.

Report of the Editor of the Journal of the American Chemical Society and Chemical Abstracts.

During the year ending November 30, 1909, 179 papers have been submitted to the Board of Editors of the *Journal of the American Chemical Society*. Of these 147 have been or will be published, 11 have been published after revision by the authors, and 21 have been returned for revision, or because they were not suitable for publication in the Journal. The number of pages printed during the last three years is as follows:

	1907	1908.	1909.
Proceedings	92	130	116
Original papers	1624	1736	1271
Reviews	73	110	64
Book reviews	73	77	31

The decrease in the number of pages published is, of course, chiefly due to the fact that papers and book reviews pertaining to industrial chemistry have been published in the *Journal of Industrial and Engineering Chemistry* during the current year. The circulation of the *Journal of the American Chemical Society* for December was 4601 copies, an increase of 628 above the circulation of December, 1908. The edition of the January number for 1910 will be 5700 copies.

Owing to the necessity for careful economy we have been compelled to consider very carefully, with regard to all papers submitted, both whether they represent important scientific work which will be of value to our readers and which is worthy of publication in our Journal, and also whether it is possible to present the material offered in a more concise form. I wish to express for the Board of Editors our appreciation of the very kind way in which our criticisms in both directions have been met, and for the assistance which has been given us by our contributors toward securing the publication of all desirable material, without exceeding the sum which was appropriated for the publication of the Journals.

At the beginning of the current year the extended table of contents in *Chemical Abstracts* was discontinued, chiefly from motives of economy, and because it was thought wise to expend the money in other directions. For the same reason the abstracts published during the year have been more carefully examined for the purpose of eliminating those which were of greater length than our funds will permit. The result has been rather an increase in the uniformity of character of the abstracts than any further shortening of those abstracts which were already in a very concise form. It has been possible as a result to publish a larger number of abstracts without increasing the number of pages. The system of checking our abstracts against those published in other abstract journals, and also to avoid duplicate publication, has been further improved, and we think it fair to say that the whole field of chemical publications in the world is more completely covered by *Chemical Abstracts* than by any other similar publication. This will be apparent from the number of abstracts published during the current year, which is as follows:

	1907.		1908.		1909.	
	No. of pages.	No. of abstracts.	No. of pages.	No. of abstracts.	No of pages.	No. of abstracts.
Apparatus	31.8	100	57.2	265	42.7	267
General and Physical Chemistry	162.6	529	268.3	1013	254.1	1081
Radioactivity	26.9	99	55.3	228	34.2	163
Electrochemistry	44.3	132	77.4	240	73.0	312
Photography	12.0	43	29.9	139	14.1	77

[1] Not included in the total.

Report of the Journal of Industrial and Engineering Chemistry for the Year 1909.

The *Journal of Industrial and Engineering Chemistry* has completed its first year and has published twenty-four editorials, one hundred sixty-eight original papers, or a total of one hundred and ninety-two articles all told. There are on hand at the present time sixteen unpublished articles and during the year there have been rejected twenty-eight articles, making a total number of articles received during the year of two hundred and forty-four.

The articles published have been distributed in the various fields as follows: Chemical Engineering, four; Heavy Chemicals, eleven; Fuels, nine; Glass, none; Metals in general, two; Iron and Steel, nine; Metallurgy of Gold, Silver, Copper, one; Metallurgy of Lead, Zinc, etc., three; Fertilizers, eleven; Pharmaceutical, Essential Oils, etc., eight; Explosives, two; India Rubber, four; Sugar and Starch, five; Water, Sewage and Sanitary Chemistry, three; Foods, thirty; Ceramics, one; Paper, none; Paints and Varnish, Resins, three; Cement, Lime, Plaster, three; Textiles and Dyeing, none; Destructive Distillation and Petroleum, six; Asphalt, Tar, Pitch, etc., four; Oils and Fats, Soaps, Lubrication, nine; Brewing and Spirituous Liquors, one; Gas and Illumination, two; Electro Chemistry, three; Analytical and Apparatus, thirty-four; Soils and Agricultural, ten; Chemical Education, three; Miscellaneous, twelve.

The monthly edition has varied from 5200 to 4600 copies. Some of the issues are now nearly exhausted.

There are increasing evidences that the Journal is finding favor abroad, particularly in England and in France.

It may be well to recall at this time the various steps which led to the establishment of the *Journal of Industrial and Engineering Chemistry* and of the separate features of the Journal. Following an agitation on the part of the industrial chemists belonging to the Society, for more representation in the affairs of the Society and for more published matter devoted to their interests, the idea of an "Industrial Journal" was first seriously discussed in the summer of 1907 at the Toronto meeting. At that meeting a committee was appointed to consider the matter in all its details and to report at the Chicago meeting, in the winter of 1907–1908. This committee, after correspondence and discussion in meetings, agreed upon the general plan of the *Journal of Industrial and Engineering Chemistry* as it exists to-day, and the Council, after a full and open discussion, adopted the report at the Chicago meeting. Appropriations for the Journal were passed at the Baltimore meeting in the winter of 1908–1909. Each department which has been established in the *Journal of Industrial and Engineering Chemistry* was established by unanimous vote of the committee which had the original plans in charge and by unanimous vote of the Council after a full discussion. It should be remembered that there were good reasons for establishing each department of the Journal or it would not have been established. There are equally good reasons for continuing the department until it is shown to be without value to a considerable number of our membership.

A scientific society which undertakes to publish journals for its members, it is not in the position of a private person or corporation, which publishes papers in the interests of a more or less narrow group of readers and in the interests of his advertisers. A scientific monthly published by a society is usually an outgrowth of the publication of the proceedings of the annual or semi-annual meeting; that is, in the early days of many scientific societies, when the number of members is rather limited, the society's funds will only permit the publication of an annual or semi-annual volume of proceedings which includes papers and sometimes discussions presented at those meetings. As the society grows, to facilitate prompt publication, a monthly may be established to take the place of the earlier proceedings. And such a publication, no less than the proceedings, is bound to publish all worthy research papers submitted. In considering what constitutes suitable material for publication, consideration must be had of several points. In the first place, a society in entering the publication field, particularly with a monthly journal, has several duties to perform. It is the paramount duty of such a society to publish suitable research material which its members present for publication. This duty of a society, if it publishes at all, must not be overlooked or underestimated, for any reason or consideration whatsoever. This is the essential point wherein a society publication differs from a private one. In the second place, in the case of a journal like the *Journal of Industrial and Engineering Chemistry*, the Society owes a second duty to its members, in the way of publishing material for the better information of its members, which is mainly of temporary interest. Such material may be in the field of engineering chemistry, of the nature of book reviews, new book lists, lists of new patents, industrial and trade notes, discussion and correspondence, or merely personal notes. In the third place, a society in entering the field of publication, owes a duty to the scientific world at large, which consists in publishing the original research papers of its members, which may have little immediate value but which must go on record and so become available for the future scientific public.

It is interesting to note that each man who is interested in a particular subject, regrets that more papers on his subject are not published. This tendency is as natural as it is regrettable. What we should desire is a well-rounded Journal with some papers during the year on each branch of the subject which it endeavors to cover.

Recently a large number of letters were sent out to authors of papers published in the *Journal of Industrial and Engineering Chemistry* during the year, asking for their views on various features of the Journal. Some new suggestions were offered which will unquestionably prove of future benefit, and some criticisms were made, but it is interesting to note that the consensus of opinion as expressed in these letters was decidedly in favor of the *Journal of Industrial and Engineering Chemistry,* as it stands at the present time, inclusive of all its established features. Probably no higher tribunal could judge of the matter than this, unless it should be the whole body of the Society, which is obviously impossible.

The principal necessity which the year has developed is to separate the papers on agricultural and food chemistry from the *Journal of Industrial and Engineering Chemistry* and publish them in a *Journal of Agricultural and Food Chemistry.* Following this, to publish more papers of an engineering chemical nature in the *Journal of Industrial and Engineering Chemistry.* This is an excellent policy. Both Journals would be eminently successful. It would mean a better classification of other material and it would mean that more and better papers on industrial and engineering chemistry would be produced and published. Practically all the material during the past year has come without solicitation. This was necessary because of the fact that funds appropriated for the *Journal of Industrial and Engineering Chemistry* for the year were insufficient to publish all material received. With the successful growth of the Society if we practice economy, we are assured of sufficient funds in the future for all our reasonable undertakings. We can therefore solicit good papers from known authorities on various subjects in the field of engineering chemistry. Your editor has no doubt that a large number of such papers could be obtained, and with such papers available for publication, assurance could be given of a far more useful Journal than has been published up to the present time. In conclusion, it appears that the *Journal of Industrial and Engineering Chemistry* has been founded on sound principles; that it rests upon a firm foundation financially, is demonstrated by the present year's experience, and that with reasonable support it can continue to be most useful to our membership, supplementing our other publications in its particular field. W. D. RICHARDSON.

Treasurer's Report.

ALBERT P HALLOCK,
Treasurer.

Report of the Finance Committee of the American Chemical Society for the Year 1909.

Your committee has during the past year examined and passed upon all the bills sent to the Treasurer for payment and has employed the firm of J. Yalden & Co., certified accountants, to audit the books of the Treasurer and their report is submitted herewith. They find that the accounts of the Treasurer have been carefully and accurately kept and they expressed their entire approval of our present system of accounting.

Respectfully submitted,
PARKER C. MCILHINEY,
GEO. C. STONE,
E. G. LOVE.

Report of the Librarian for the Year 1909.

No additions of especial importance have been made to the Library during the past year. Periodicals received in exchange for the Society's publications have, so far as possible, been bound and added to the Library files. At present the Library contains about 6000 volumes and pamphlets.

LIBRARIAN'S ACCOUNT.

E. G. Love, *Librarian.*

Division of Industrial Chemists and Chemical Engineers.

The meetings of the Division were held on Tuesday, Thursday and Friday with Chairman A. D. Little presiding. A full account of their proceedings with list of papers will be found in the February number of the *Journal of Industrial and Engineering Chemistry.*

A special feature was the symposium on the Chemistry of Paint, held Thursday morning, which evoked a lively discussion and at which many interesting points were brought forward besides the important papers that were presented.

Committees of unusual importance to industrial chemists and to the chemical trade were appointed and will be found in the full proceedings. These committees consisted of a Committee on Definition of Trade Terms, Clifford Richardson, *Chairman;* Committee on Trade Customs, Henry Howard, *Chairman;* Committee on Official Specifications, Hervey J. Skinner, *Chairman;* Committee on Research Problems, Geo. C. Stone, *Chairman;* Committee on Standard Methods of Technical Analysis, T. J. Parker, *Chairman;* Committee on Descriptive Bibliographies, Clement W. Andrews, *Chairman;* Committee on Publicity, Wm. McMurtrie, *Chairman;* Special Committee to Confer with Manufacturers for the Purpose of Determining at What Prices Elements and Special Compounds Can Be Obtained Provided a Large Market Is Developed for Them, Gellert Alleman, *Chairman.*

The officers elected for the year 1910 are as follows:

Chairman, A. D. Little; *Vice-Chairman,* Geo. C. Stone; *Secretary,* F. Gallagher, 93 Broad St., Boston, Mass.; *Executive Committee,* The officers and W. D. Richardson, *ex-officio* and W. H. Walker, J. O. Handy, A. S. Cushman, C. P. Van Gundy, L. A. Olney.

B. T. BABBITT HYDE, *Retiring Secretary.*

Division of Physical and Inorganic Chemistry.

The Division met on Tuesday, Thursday and Friday, presided over by Chairman C. H. Herty.

At the business session the following officers were elected for 1910: *Chairman,* E. C. Franklin; *Vice-Chairman,* Alexander Smith; *Secretary,* S. L. Bigelow, Ann Arbor, Mich.; *Executive Committee,* Officers *ex-officio* and W. F. Hillebrand, G. A. Hulett, W. L. Miller, T. W. Richards, H. P. Talbot.

The question of forming a Section of Inorganic Chemistry was brought before the meeting and the Executive Committee was instructed to consider the advisability of forming such a Section, to report to the Council at the San Francisco Meeting if possible. To facilitate matters the Chairman appointed a committee to consider the matter and to report to the Executive Committee. This committee consisted of A. W. Browne, W. F. Hillebrand, T. W. Richards, Alexander Smith, H. L. Wells.

The following papers were presented to the Division:

Some Observations on Phosphorescence. W. L. Dudley.

Solarization without Light. W. D. Bancroft.

Electro-Chemical Investigation of Amalgams of Thallium, Indium, Tin, Lead, Zinc and Cadmium. T. W. Richards, J. Hunt Wilson and R. N. Garrod-Thomas.

The Reduction of Zinc by Mercury and the E. M. F. of Zinc Amalgams. J. L. Crenshaw.

Rôle of Water in Minerals. W. F. Hillebrand.

Ammonolysis of Hydrazine Sulphate. A. W. Browne and T. W. B. Welsh.

Quantitative Application of the Theory of Indicators to Volumetric Analysis. experimentally illustrated. Arthur A. Noyes.

Measuring Capillary Ascension in Metal Tubes. S. L. Bigelow.

The Electrolysis of Copper Sulphate Solutions with Intermittent Current. W. Lash Miller.

The Final Results of an Investigation on the Atomic Weights of Lithium and Silver. T. W. Richards and H. H. Willard.

A Revision of the Atomic Weight of Phosphorus. G. P. Baxter and Grinnell Jones.

A Revision of the Atomic Weight of Neodymium. G. P. Baxter and H. C. Chapin.

The Velocity of Saponification of Formic Esters. Julius Stieglitz.

The Influence of Acids and Alkalies upon the Activity of Invertase. C. S. Hudson and H. S. Paine.

Heats of Combustion of Organic Isomers. T. W. Richards and R. H. Jesse, Jr.

Specific Heat and Heat of Neutralization of Aqueous Solutions. T. W. Richards and A. W. Rowe.

The Nature of Attractive Forces. J. E. Mills.

Changes in Volume during Solution of the Alkali Halides. G. P. Baxter.

A Simple Dynamic Method for Determining the Boiling Points and Vapor Pressures of Liquids or Solids with Small Amounts of Material. Alexander Smith and Alan W. C. Menzies.

The Compressibilities of Organic Isomers. T. W. Richards, J. H. Mathews and C. L. Speyers.

The Solubility of Salts in Concentrated Solutions. Arthur E. Hill.

A Method for Determining Vapor Pressures. Alexander Smith and Alan W. C. Menzies.

A Redetermination of Vapor Pressures of Water and Mercury. Alexander Smith and Alan W. C. Menzies.

On the Oxalates of Hydrazine. J. W. Turrentine.

Some New Double Arsenates. Louis J. Curtman.

A Quantitative Study of the Constitution of Calomel Vapor. Alexander Smith and Alan W. C. Menzies.

Wire Silver in Ores and How It Is Formed. C. E. Swett.

The Electrical Deposition of Zinc. Elwood B. Spear.

The Determination of Antimony by the Gutzeit Method. Charles R. Sanger.

Molybdenum and Tungsten. Colin G. Fink.

Caesium Nitrate and the Mass Action Law for Strong Electrolytes. E. W. Washburn and D. A. McInnes.

Cryoscopic-Cryohydric Studies. S. C. Lind.

The Influence of Temperature on the Formation of Water Gas. J. K. Clement and L. H. Adams.

A Method for Determining the Molecular Weights of Dissolved Substances by Measurement of Vapor Pressure. Alan W. C. Menzies.

The Condensation of Water by Electrolytes. F. K. Cameron and W O. Robinson.

The Hydrolysis of Raffinose by Invertase. C. S. Hudson.

A Relation between the Chemical Constitution and the Optical Rotatory Power of the Sugar Lactones. C. S. Hudson.

A Constant Temperature Regulator. Edward Bartow and Frank Bachmann.

A New Method of Separating Chlorine, Bromine and Iodine. Louis Kahlenberg.

The Estimation of Radium Emanation and of Radium in Common Materials. Merle Randall.

The Solubility Relations of Calcium Sulphate at High Temperatures. Arthur C. Melcher, presented by A. A. Noyes.

A New Test Tube Holder. H. Emerson Wetherill.

Notes on the Preparation of Chromyl Compounds. Harry S. Fry.

The Reaction between Bromic and Hydriodic Acid in Concentrated Hydrochloric Acid Solution. D. L. Randall.

On the Velocities of Certain Reactions between Metals and Dissolved Halogens. Ralph G. Van Name and Graham Edgar.

A New Method of Determining the Potentials between Liquids. Gilbert N. Lewis.

Forces at the Boundary between Two Liquids. W. D. Harkins.

Ionization of Salts in Mixtures with a Common Ion. W. C. Bray and F. L. Hunt.

Ionization of Salts in Mixtures with no Common Ion. Miles S. Sherrill.

Chlorsulphonic Acid and Pyrosulphuryl Chloride. Charles R. Sanger.

The Electrical Conductivity of the Alcohols in Liquid Hydrogen Chloride. E. H. Archibald.

Metallic Titanium. Matthew A. Hunter.

The Chief Determining Factor in the Toxicity of the Metal Ions. L. L. Woodruff and H. H. Bunzel.

The Solubility of Gold in Nitric Acid. Frederick P. Dewey.

The Direct Estimation of all Intensities of Hydrogen Ion Concentration by Means of Di-nitro-hydrochinone. Lawrence J Henderson.

The Nitrogen Thermometer from Zinc to Palladium. A. L. Day and R. B. Sosman.

W. D. BANCROFT, *Retiring Secretary.*

Division of Fertilizer Chemistry.

The meeting of the fertilizer chemists was held on Thursday, December 30th, and was presided over by the Chairman, F. B. Carpenter.

The Secretary's report showed 106 members enrolled in the Division.

At the business meeting the following officers were elected for the year 1910: *Chairman,* F. B. Carpenter; *Vice-Chairman,* B. L. Hartwell; *Secretary and Treasurer,* J. E. Breckenridge, Carteret, N. J.; *Executive Committee,* Officers *ex-officio* and F. P. Veitch, H. A. Huston, W. J. Gascoyne, P. Rudnick.

The Chairman's address, entitled "Influence of Chemistry on Agriculture," was presented before the Division. A more detailed account of the meeting with papers read will appear in the February number of the *Journal of Industrial and Engineering Chemistry.*

J. E. BRECKENRIDGE, *Secretary.*

Division of Agricultural and Food Chemistry.

The Division met on Thursday and Friday, presided over by *Chairman* W. D. Bigelow. The officers elected for the year 1910 are: *Chairman,* C. D. Woods; *Vice Chairman,* G. E. Colby, *Secretary,* B. E. Curry, Durham, N. H.; *Executive Committee,* Officers *ex-officio* and E. W. Hilgard, H. W. Wiley, J. P. Street, C. G. Hopkins.

The address of the Chairman, W. D. Bigelow, entitled "The Construction and Installation of a Technical Laboratory," was presented before the Division. In addition to this many papers were presented. Several of these, owing to lack of time and absence of authors, were read by title. The meeting was regarded as an unusually interesting one on account of the wide variety of subjects treated and because of the very full discussion which was entered into by the members in attendance.

Details of the meeting with a list of papers read will appear in the February number of the *Journal of Industrial and Engineering Chemistry.*

F. M. DORSET, *Secretary pro tem.*

Division of Organic Chemistry.

The Division met on Tuesday and Thursday, with Chairman R. S. Curtiss presiding. On Tuesday morning a special program was arranged which was very largely attended by the members of the Society and consisted of the following two papers:

1. Virgil Coblentz. "Synthetic Medicinals: Recent Progress in Relationship between Physiological Action and Structure."

2. Hugo Schweitzer. "Some Recent Advances in the Chemistry of Coal-Tar Colors."

The Chairman's address was presented in general session.

The Secretary reported 174 registered members of the Division.

The following officers were elected for the year 1910: *Chairman*, E. C. Franklin; *Vice-Chairman and Secretary*, R. H. McKee, Orono, Maine; *Executive Committee*, Officers *ex-officio* and H. A. Torrey, J. Stieglitz, J. E. Bucher.

The following motion of general interest was passed:

"The Division of Organic Chemistry of the American Chemical Society recognizes the great usefulness to chemical research, especially organic research, of the plan as now carried out by the Association of American Chemical Research Laboratories[1] and the even great possibilities of the plan suggested for the Chemists' Club of New York City[2] and wishes to express its approval of these plans."

It was further voted:

That the Executive Committee be and hereby is directed to consider this matter and determine if it is desirable that the Division of Organic Chemistry take further action with regard to it.

The following papers were presented to the Division:

The Action of Acetylene on Iodine Trichloride. H. Edmund Wiedemann.

The Condensation of Methylethyl-ketone by Acids and Alkalies. Alfred Hoffman.

4- and 5-Acetamino Acetanthranils and Quinazolines Derived Therefrom. Marston T. Bogert and C. G. Amend.

Ethyl Phenylimino-malonate and Its Reaction. Richard S. Curtiss and F. Grace C. Spencer.

Melting and Boiling Points of Certain Disubstitution Products of Benzene. J. Bishop Tingle.

Phthalamidic Acids Substituted in the Benzene Nucleus. J. Bishop Tingle and S. J. Bates.

The Constitution of Retene and Its Derivatives. John E. Bucher.

Stereoisomeric Chloromido Ketones. Julius Stieglitz.

The Properties of the Hexa-Substitution Products of Ethane. James F. Norris.

Studies in Tautomerism. S. F. Acree.

Furylacetic Ester and Furyl-Pyrazolones. Henry A. Torrey and J. E. Zanetti.

Hydrazones of Certain Oxy-Ketones; Alkali Insoluble Phenols. Henry A. Torrey.

The Preparation of Styrolene Alcohol. Wm. Lloyd Evans and Lou Helen Morgan.

The Basic Properties of Oxygen; Compounds of Dimethylpyrone and the Halogen Hydrides. D. McIntosh.

The Constitution of Ortho-Benzo-Quinone. Wm. McPherson and Howard J. Lucas.

[1] *Science*, 30, 645.

[2] *Ibid.*, 30, 667.

Esterification and Steric Hindrance. M. A. Rosanoff, C. D. Wright and T. F. Power.

The Constitution of the Carboxonium Salts. M. Gomberg and L. H. Cone.

The Constitution of the Carbothionium Salts and of the Acridine Salts. M. Gomberg and L. H. Cone.

Glycogen Content of Beef Flesh. P. F. Trowbridge and C. K. Francis.

The Constitution of Benzene from the Standpoint of the Corpuscular-Atomic Conception of Positive and Negative Valences. Harry Shipley Fry.

The Formation of Cyclopentadiens. William J. Hale.

Some Organic Compounds of Selenium. Howard W. Doughty.

A Measure of Thermodynamic Positivity and Negativity in Water Solution with Reference to Chemical Reactions of Organic Compounds. C. G. Derick.

The Addition Power of Methylethyl-ethylene. Roger F. Brunel.

Equilibrium at High Temperatures between Isobutyl Bromide and Tertiary Butyl Bromide. Roger F. Brunel.

The Iodine Compound of Pinene and the Resin Formed by the Action of Iodine on Pinene. G. B. Frankforter and B. F. P. Brenton.

RALPH H. MCKEE, *Secretary.*

Division of Pharmaceutical Chemistry.

The Division met on Thursday, December 30th, with Chairman A. B. Stevens presiding.

The by-laws were presented and were adopted by the Division. These will, as required by the Constitution, be referred to the Council for approval.

The following officers were elected for the year 1910: *Chairman*, A. B. Stevens; *Vice-Chairman*, J. M. Francis; *Secretary*, B. L. Murray, c/o Merck & Co., University Place, New York City; *Executive Committee*, Officers *ex-officio* and J P. Remington and Edward Kremers.

The following papers were presented:

Scope of Pharmaceutical Chemistry. A. B. Stevens.

Pharmacopoeial Tests for Ammonium Benzoate. A. Seidell and G. A. Menge.

Strychnine Sulphates. A. B. Stevens.

The Botanical Source of the Crude Drug Known as Wild Yam. H. H. Bartlett.

On the Availability of "Idophenine" in the Separation of Acetanilid and Acetphenetidin. W. O. Emery.

Detection of Colocynth Seed in Powdered Colocynth. V. K. Chesnut

"Analytical Notes on Gamboge." Frank O. Taylor.

"On the Melting Point of Aconitine." Frank O. Taylor.

Pancreatin. John P. Street.

The Relation of the Chemist to Proprietary Medicines. W. A. Puckner.

The Purity Rubric and the U. S. P. Tests, with Notes on Quantitative Methods for Certain Pharmacopoeial Compounds. Atherton Seidell and M. I. Wilbert.

Chairman of the Delegates of the American Chemical Society to the Pharmacopoeial Convention presented a report and led a discussion in regard to matters to be brought before that Convention. Geo. D. Rosengarten.

B. L. MURRAY, *Secretary.*

Section of Chemical Education.

The Section of Chemical Education met on Tuesday and Thursday, presided over by Lyman C. Newell, Chairman The Chairman's address, however, was read in general session on Wednesday.

A special feature of the meeting was the discussion of problems relating to secondary school chemistry.

The following resolutions after careful discussion were unanimously passed:

Resolved, That it is the sense of this Section that there is an urgent need for an improvement in the conditions under which chemistry is taught in secondary schools in that

1. The time allotted to the subject in the ordinary curriculum is not sufficient.
2. The chemistry teacher should not teach other subjects requiring laboratory preparation.
3. Provision should be made, by supplying suitable paid help and by allowing the teacher sufficient time each day during school hours, for the preparation of laboratory material.
4. The teacher should be permitted to purchase, subject to suitable supervision of his vouchers, supplies for current consumption, either from petty cash account or from definite appropriation.
5. Text-books should not be used without the approval of chemistry teachers.
6. A double laboratory period should be considered the equivalent of a single formal recitation.

EDWARD ELLERY,
ALBERT L. SMITH,
M. D. SOHON,
Committee.

About 50 were in attendance.

The following papers were presented:

On the Purpose and Method of the Chemistry Course in the Public High School. Frank B. Wade.

Content and Method of a First Course in Chemistry. M. D. Sohon.

Elementary Chemistry in Vocational Education. Lyman G. Smith.

Conditions under which Secondary School Teachers Conduct Their Work. Albert L. Smith.

Conditions and Equipment in Secondary Schools. Charles R. Allen.

The Case against Qualitative Laboratory Experiments. Edward Ellery.

The Desirability of the More Careful Teaching of the Miscibility of Common and Uncommon Reagents. Charles S. Palmer.

Elementary Chemistry Teaching as a Means of Developing the Power of Independent Scientific Reasoning. Arthur A. Blanchard.

The Teaching of Chemistry in Secondary Schools. Mosby G. Perrow.

Educational Value of Chemistry. W. S. Leavenworth.

The First Course in Chemistry for Secondary Schools. M. D. Sohon.

Section of Biological Chemistry.

The Section met on Thursday in the Lowell Building in joint session with the American Society of Biological Chemists.

The following papers were presented:

Industrial Bacteriology as a Field for Bio-Chemical Investigation. Samuel C. Prescott.

Studies upon the Physiological and Chemical Toxicology of the Sap of the Manzanillo Tree. Jose A. Fernandez Benitez.

The Phosphorus of the Flat Turnip. Burt G. Hartwell and Wilhelm B. Quantz.

Concurrent Oxidizing and Reducing Power of Roots. Oswald Schreiner and M. X. Sullivan.

Ratio of Plant Nutrients as Affected by Harmful Soil Compounds. Oswald Schreiner and J. J. Skinner.

Some Points in the Analysis of Proteins. T. B. Osborne.

A Method for the Determination of Amino Nitrogen and Its Applications. Donald D. Van Slyke.

The Anaphylactic Reaction as a Specific Test for Protein. M. J. Rosenau.

The Manganese-bearing Tissues of the Fresh Water Mussels. H. C. Bradley.

The Determination of Arsenic in Animal Tissues. Charles R. Sanger.

The Estimation of Morphine in Cases of Poisoning. Charles R. Sanger.

The Selective Antiseptic Action of Copper Salts. Alfred Springer.

Stagnation *vs.* Circulation in House Air. Ellen H. Richards and Royce W. Gilbert.

The Relation of Typhoid Fever to the Water Supplies of Illinois. Edward Bartow.

Destruction of the Enzym Invertase by Acids and Alkalies. H. S. Paine

The Action of Enzymes on Sugars. C. S. Hudson.

The Cause of Depression Produced by Molasses. J. B. Lindsey.

The Chemical Organization of a Typical Fruit. A. E. Vinson.

Fixing and Staining Tannin in Plant Tissues. A. E. Vinson.

Cornin: a Glucoside Obtained from Cornus Florida. E. R. Miller.

India Rubber Chemistry Section.

The Section met on Thursday, December 30th, under the chairmanship of Mr. Charles C. Goodrich, of New York City. Mr. Frederick J. Maywald, 89 Pine St., New York City, was elected Secretary and the Section requested that these officers act pending the probable organization of a Division. 28 chemists and manufacturers of India rubber were present at the meeting, representing many of the most important rubber corporations, and decided interest was shown in the organization of a Division and in the work that it was hoped might be accomplished. A preliminary organization was effected, which can readily be made permanent whenever divisional government is granted by vote of the Council.

A committee, consisting of Chas. M. Knight, Edw. A. Barrier, Frederick J. Maywald, Milton E. MacDonald, Wm. G. Hills, Sheldon P. Thatcher, W. C. Geer, Mr. Oelschlaeger and Harvey M. Eddy, was appointed to consider the methods of analysis in examination of rubber and rubber compounds.

Much interest was shown in obtaining complete abstracts of all articles on the Chemistry of India Rubber, and a committee, consisting of H. Hughes, Harold van der Linde and M. L. Allard, was appointed to assist the regular abstractors who might be appointed to care for a special section of rubber chemistry in the *Abstracts Journal.*

A committee on membership, consisting of H. M. Eddy, H. van der Linde and Charles Knight, was also appointed.

There was considerable discussion with reference to the question of specifications for rubber goods and a committee of three, consisting of C. R. Boggs, C. E. Waters and G. H. Savage, was appointed to consider the question.

Great enthusiasm was shown throughout the meeting and there is every reason to hope that a strong and active Division of Rubber Chemistry may be formed. F. J. MAYWALD, *Secretary.*

All of the above minutes abstracted and edited from the originals which are held on file. CHARLES L. PARSONS,
Secretary Amer. Chem. Soc.

COUNCIL.

The requirement of the Post Office Department being that such portion of the payment made by members ascribed to membership dues should be entirely separated in our By-laws from the amount paid for subscriptions, the Council, after the required three weeks' notice, have unanimously voted to change By-laws 14:

> The annual dues of members shall be $2.50, the subscription charges for members subscribing to the publications of the Society shall be $7.50, both annual dues and subscription charges to be payable in advance on the first day of January of each year. Persons elected to membership after October of any year shall not be required to pay annual dues for that year.

to read:

> By-law 14.—The annual dues of members shall be $2.50, payable in advance on the first day of January of each year. Persons elected to membership after October of any year shall not be required to pay annual dues for that year. The payment of membership dues does not entitle the member to receive any of the publications of the Society entered by the Post Office Department as second-class matter.

and to have the subscription rates made and legalized by vote of the Directors instead of being a part of the By-laws.

The following changes in the By-laws have also been made by the Council to bring the By-laws into conformity with the requirements above mentioned:

> By-law 15.—Any newly elected member upon the payment of the subscription charges for the year in which he is elected shall be entitled to receive all the publications of the Society for that year.
>
> By-laws 16.—Any member in arrears for subscription charges for two months shall not thereafter receive the journals of the Society until all his arrears are paid.

Boston Meeting.

The Council met at the Hotel Lenox on Monday evening, December 27th, at 8.30 o'clock, with President Whitney in the chair and the following members present: W. R. Whitney, C. L. Parsons, H. P. Talbot, Edw. Bartow, S. W. Parr, Louis Kahlenberg, F. C. Phillips, Morris Loeb, L. P. Kinnicutt, W. D. Bancroft, Chas. Baskerville, C. H. Herty, Alfred

Springer, W. D. Richardson, A. Lowenstein (substitute for G. Thurnauer), M. T. Bogert, W. A. Noyes, G. C. Stone, G. P. Adamson, A. D. Little, A. A. Noyes, A. W. Browne (substitute for L. M. Dennis), Wm. Brady, R. S. Curtiss, L. H. Baekeland, W. R. Smith, Wm. McPherson, T. J. Parker, E. G. Love, W. F. Hillebrand, G. B. Frankforter, W. T. Taggart, Alex. Smith, J. H. Long, W. L. Miller, C. A. Catlin, L. A. Olney, A. M. Comey (substitute for G. E. Barton), A. P. Hallock, J. F. Norris and W. H. Walker.

It was voted that the President and the Secretary be empowered to arrange for the San Francisco Meeting and fix the date thereof.

It was voted that the report of the committee approving the By-laws of the Organic Division be accepted and the By-laws approved by the Council.

It was voted that a committee be appointed with power to pass upon the constitutionality of the By-laws submitted by the Division of Fertilizer Chemistry and to approve them for the Council. President Whitney has appointed H. W. Wiley, F. C Cameron, C. S. Hudson.

It was voted that the By-laws of the Division of Physical and Inorganic Chemistry be referred back to the Division to make two slight changes necessary to bring them into conformity with the Constitution and By-laws of the Society and that when these changes are made the By-laws be approved.

It was voted that a Directory of the Society be published during the summer months as a separate to be distributed to members and others under conditions laid down by the Directors of the Society which shall properly safeguard the use of the list from those who wish it for advertising purposes.

A motion having been made in regard to granting special privileges to undergraduate student members, it was voted to refer the matter to a committee to consider same and report back to the Council. President Whitney appointed A. A. Noyes, T. W. Richards and H. P. Talbot members of this committee.

It was voted that a paper be circulated by a committee appointed by the Chair to secure subscriptions to the fund for a monument to Marcelin Berthelot and that the amount of subscription received be sent as a contribution from the members of the Chemical Society and that if it does not reach one thousand francs, it be referred again to the Council The Chair appointed M. T. Bogert, Chas. Baskerville and W. Lash Miller

The following resolutions on the death of Charles Benjamin Dudley were presented by H. P. Talbot and unanimously adopted by the Council, all members rising.

Resolutions on the Death of Charles Benjamin Dudley.

In the death of Charles Benjamin Dudley, which occurred on December 21, 1909, the American Chemical Society has lost one of its most valued members, whether measured by the length of association with its affairs, by the wisdom and helpfulness of his counsel, or by his loyalty to its interests.

The Council of the Society desires to record its sense of deep appreciation of the services rendered to the Society by Dr. Dudley, both as a member from the time of its organization, as a long-time member of its Council and Board of Directors, and as its President.

By his professional accomplishments, especially in the field of applied chemistry, and in particular by his successful efforts to place the business relations between manufacturer and consumer upon an intelligent, accurate, and equitable basis, Dr. Dudley had won an enviable renown, fully recognized by the Council. This success was largely made possible by his high integrity, his quiet sense of equity, his courage in maintaining a carefully formed opinion and his uniformly lovable character—traits which also endeared him to all his associates, to whom his death brings a sense of personal loss.

The Council of the American Chemical Society votes, therefore, to spread this entry on its minutes and to extend its deep sympathy to the members of his family in their days of sadness.

It was voted that a committee be appointed by the President to consider the matter of the publication and distribution of papers read before the general meetings of the Society or its Local Sections when such papers are adjudged by the Editors for any reason unsuited for publication in the Journal, although of value and interest to members. The President appointed Francis C. Phillips, W. A. Noyes and H. P. Talbot.

The following committee report was then presented by A. D. Little, in the absence of Chairman Veitch and it was voted that the report be received, published in full in the Journal, and that the committee be retained and be thanked for its efficient work.

Report of the Paper Committee of the American Chemical Society.

December, 1909.

At the June meeting of the Society in 1908 at Mr. Veitch's request, Mr. Tolman laid before the Council some results which the former had obtained on the paper then used in the *Journal of the American Chemical Society* and *Chemical Abstracts*, which brought out the fact that this paper did not comply with the specifications, was of low quality and needlessly heavy and bulky. The Council, on motion of Mr. Tolman, appointed a committee consisting of Dr. W. A. Noyes, Dr. McMurtrie, Mr. A. D. Little, Mr. M. L. Griffin and Mr. Veitch to "consider the quality of the paper used in the Journals" and to secure, if practicable, more suitable papers. The committee worked under difficulties. The funds of the Society were limited and therefore the total cost of printing and mailing the journals could not be increased, and, furthermore, as the members of the committee live in different parts of the country most of its work has been done through correspondence with its attendant delays.

In the execution of its duties it has been the purpose of the committee to secure the most durable, strongest, lightest, thinnest, most opaque and cleanest paper, having a surface not injurious to the eyesight, that it was possible to procure for the money available.

The problem is complicated by the fact that certain characteristics which a paper should have are diametrically opposed to other equally, or more, important qualities. Thus lightness and thinness are secured at the expense of opacity, while opacity means greater thickness and weight, or less strength and durability. In a paper of a given weight and thickness opacity is secured at the sacrifice of strength and durability; lightness and thinness are secured at the sacrifice of strength, durability and opacity. It is evident, therefore, that any paper must be a compromise among opposing characteristics and the nature of this compromise is determined by the purpose for which the paper is to be employed In effecting this compromise the committee steadily endeavored to maintain essentials and to accentuate utility. The committee recognizes that there are members of the Society who would much prefer what they would declare is a better-appearing paper, one that is thicker, stiffer and less transparent. This view has not been ignored by the committee. It is believed, however, that the briefest consideration of the subject and the most cursory comparison of the current issues, particularly the bound volumes, with those of last year will furnish convincing evidence in support of the action of the committee.

The advantages of the paper used this year are at once apparent. The current volume of *Chemical Abstracts* will be bound in two, while the 1908 issues were bound in three volumes, a saving of one-third on the cost of binding. The shelf space and weight per volume of the same number of pages is also reduced approximately one-third. The publications are much more convenient to handle, and are more safely and economically stored, both important considerations to the reader and to the librarian.

It was difficult to secure an acceptable paper at a price which the Society could pay. The specifications are more stringent than it is customary to draw for paper of this class. Paper-makers prefer to make heavier and thicker paper, as more can be produced for the same operating expenses, and further, the printer feared the new paper would not work satisfactorily on the presses, and urged that no change be made. All of these difficulties and objections were finally overcome and a paper made to comply with the following specifications was secured:

Stock.

Rag	75 per cent.
Bleached chemical wood or equivalent thereto	25 "
Ash—China clay	5 "
Weight (26 × 38, 500)	42 pounds.
Strength (Mullen)	15 "
Folding number (Schopper) if practicable	10 "

Sizing $^3/_4$ rosin—no starch.
Finish—uniform machine, same on both sides.
Color—uniform, natural.
Paper must be well washed to remove soluble salts and bleaching materials.

The comparative value of the old and new papers is shown except so far as opacity is concerned, by the following statement of the composition, strength, and folding qualities of the papers:

Stock.	Old.	New.
Rag	20 per cent.	77–81
Bleached chemical wood	80 "	23–19
Ash	12–20 "	6.4–8.7
Weight—ream 26 × 38, 500 lbs	60 "	40–42
Thickness, thousandths inch	3.8 "	3.0
Double folds (weak direction)	2 "	3–4
Strength, Mullen	5–10 pounds.	12–14.5

From these specifications it is clear that the paper now used is much superior in durability and strength to that formerly used and it was estimated would cost no more for a year's supply. In confirmation of the opinion of the committee on the question of cost it may be interesting to know that in a letter to Dr. Noyes, dated February 4, 1909, the printer states that the postage on the foreign-going February issue of the Journal was $10.50 less than it would have been if printed on the old paper and the domestic postage was $10.00 less, a total saving in postage of $20.50 on the February issue. The paper for this issue, however, cost $13.20 more than the old paper would, reducing the net saving on the new paper to $7.30. If this rate extends throughout the year on the three monthly issues of the Journal and Abstracts, the new paper, in addition to the other advantages, will have saved the Society approximately $200 per year. Doubtless the editors can give definite information on this point.

The committee has endeavored to improve this paper for 1910. It is fully realized that it will not withstand indefinitely the severe usage of library reference, such as the publications of the Society are subjected to. So far, however, improvement has not been feasible, except that the opacity has been increased by increasing the ash from 5–8 per cent. The cost of the paper has been reduced from 6.84 cents to 6.55 cents per pound.

It has not been the object of the committee to have the publications cost less, however, and though the same paper at a materially lower cost has been selected for next year's issues, the committee hopes ultimately to secure a much better paper which which may cost more.

During this year the committee has, after consultation with and the approval of Mr. Richardson, the editor, drawn the following specifications for the paper for the "Engineering and Industrial Journal":

Stock.	
Rag	60 per cent.
Bleached chemical wood or equivalent thereto	40 "
Ash	15 "
Weight, ream	100 pounds.
Thickness thousandths inch, maximum	0.0032
Strength, Mullen	15 pounds.

Sizing, rosin, no starch.
Finish, uniform, supercalendered, same on both sides.
Color, uniform, natural.
Paper must be well washed to remove soluble salts and bleaching materials.

The comparative value of the paper in the current volume and the proposed paper is indicated in the following table:

Stock.	Present paper.	New paper.
Rag	38–60 per cent.	60 per cent.
Bleached chemical wood	62–40 "	40 "
Ash	16–26.7 "	15 "

	Present paper.	New paper.
Weight ream 35 × 48, 500	120 pounds.	100 pounds.
Thickness, inch	0.0035–0.0040	0.0032
Strength, Mullen	9–14 pounds	15 pounds.
Double folds	1–2 "	not det'n.
Sizing	rosin.	rosin.

In other words, the new paper will be of better stock, will be stronger, thinner, lighter, contain less loading and will as a consequence prove more durable in service. The improvements are along the lines followed in the Journal paper, but the changes will not be so marked. The committee estimates that the saving in printing and mailing the "Industrial Journal" will approximate $200 per annum.

Consideration has been given the cover paper used on the Society's publications. It is reasonably certain that better and at the same time less expensive covers can be had. A suggestion that more distinctive colors be given the covers of the several publications has been made and the committee has the whole question of covers under consideration, upon which a decision may be reached in time for the 1910 issues.

It may not be out of place to call attention to the fact that owing to the continued deficit in the Post Office Department, serious consideration may be given by this Congress to the proposal to increase the postage on second-class matter. Should this be done the effect on the finances of the Society will be less serious than if a heavier paper were employed in its publication.

In closing this report of progress your committee would emphasize again the fact that its efforts have been against the modern print paper making practice, which emphasizes quantity rather than quality. Final results are not therefore obtained at once.

Better and more suitable paper than that so far secured for the publications of the Society can undoubtedly be obtained at once at considerably increased cost. It is believed that in time better paper may be had, at but small increase in cost. When paper makers in general are more familiar with the manufacture of this class of paper, when they become better acquainted with modern methods of paper testing and know more definitely what tests their products will comply with, there will doubtless be more competition and higher grade paper can be secured. It would seem advisable, therefore, if it meets with the wishes of the Council, to continue the committee to this end.

In conclusion it may be said that from the utilitarian viewpoint, and probably from the artistic as well, the publications of the Society have been improved and the expense of printing them materially reduced.

It was voted that W. D. Richardson and A. M. Patterson be added to the committee on paper.

The Treasurer's report was read and adopted.

It was voted that the Budget for 1910 be taken up and considered by sections.

It was voted that the question of policy in conducting the *Journal of Industrial and Engineering Chemistry* be referred to the Executive Committee of the Division of Industrial Chemists and Chemical Engineers for an expression of opinion with the request that they consider the matter and send their opinion to the Council on Wednesday evening.

It was voted that when the meeting adjourned it adjourn to reconvene immediately following the President's address on Wednesday evening.

It was voted that the question of expenses of officers and editors attending the meetings of the Society hereafter be referred to a committee to report on Wednesday evening.

Several items of the Budget were then passed and others discussed and the whole was left over for final approval as a whole for the next meeting of the Council.

The President appointed as a committee to consider the matter of expenses of officers attending meetings of the Society, Morris Loeb, W. D. Bancroft and Wm. McPherson.

A second Council meeting was held Wednesday evening, December 29th, following the President's address. The meeting was called to order with the following members present: W. R. Whitney, F. B. Carpenter, A. P. Hallock, G. P. Adamson, H. W. Wiley, A. D. Little, L. P. Kinnicutt, C. A. Catlin, G. B. Frankforter, R. E. Stallings, A. W. Browne (substitute for L. M. Dennis), A. B. Stevens, F. C. Phillips, C. L. Parsons, J. E. Mills, W. A. Noyes, J. H. Long, H. P. Talbot, Alex. Smith, W. D. Bancroft, W. D. Richardson, M. T. Bogert, Morris Loeb, E. G. Love, T. J. Parker, W. F. Hillebrand, L. A. Olney, W. R. Smith, G. C. Stone, Edw. Bartow, L. H. Baekeland, C. H. Herty, Wm. Brady, Chas. Baskerville, Alfred Springer, W. T. Taggart, S. W. Parr, A. Lowenstein (substitute for G. Thurnauer).

It was voted that the present committee in charge of the Section of Chemical Education be continued.

It was voted that the Program Committee be instructed by the Council to comply if possible with the recommendations of the committee having in charge the Section of Chemical Education to the effect that when the Section of Chemical Education arranged a program bearing especially upon the work of one of the Divisions a free half-day for the program the Section of Chemical Education be found upon which the Division concerned shall hold no program of its own, leaving it in the jurisdiction of the Program Committee, however, to arrange the matter as may be most satisfactory.

The Executive Committee of the Division of Industrial Chemists and Chemical Engineers presented their opinion in regard to the policy to be followed in conducting the *Journal of Industrial and Engineering Chemistry* as requested at the previous Council meeting. As a result of their recommendations the following motions based thereon were passed:

Voted, That all papers giving the results of good research work that are offered or can be obtained be published within the limits of the appropriated Budget.

Voted, That in addition to papers on original work others dealing with progress in any given line or with improvements or processes should be published and that three hundred dollars or as much thereof as may be necessary be appropriated for the period of six months to be used in the discretion of the editor in procuring articles coming under this recommendation.

Voted, That the question of printing the Journal throughout in 9-point type be referred to the directors with power.

Voted, That the editor of the *Journal of Industrial and Engineering Chemistry* be paid a salary of one thousand dollars per year and 5 per cent. on the advertisements secured by him up to the time an advertising agent is appointed.

Voted, That a committee of five be appointed by the chair to recommend to the directors a suitable advertising agent for employment and that W. D. Richardson and Wm. McMurtrie be members of the committee. President Whitney appointed A. D. Little, W. D. Richardson, Wm. McMurtrie, W. H. Walker and Geo. P. Adamson.

Voted, That the Board of Directors upon such recommendation from the committee be authorized to employ an advertising agent on a commission basis, such commission not to exceed 25 per cent.

It was voted that the question of publishing a separate *Journal of Agricultural and Food Chemistry* be referred to a committee to be selected by the President of the Society in conjunction with the Executive Committee of the Division of Agricultural and Food Chemistry and that copies of the report of this committee be sent to all members of the Council by mail not later than June 1, 1910.

Dr. Loeb reported for the committee appointed at the previous meeting to make recommendations in regard to the expenses of officers at General Meetings and the following recommendations of the committee were unanimously adopted.

1. That the railroad and hotel expenses of the President and the Secretary be paid at both the annual and the summer meeting.
2. That the traveling expenses be paid for the Treasurer and Editors in attendance at the annual meeting.
3. That if the Board of Directors desire to present a special recommendation to the Council at a summer meeting which affects the work of one of the officers, such officer shall be previously notified and if he desires to be heard in opposition shall be paid his traveling expenses.

It was voted that the item of clerical expense for the Editor of the *Journal of Industrial and Engineering Chemistry* be referred to the Directors with power to arrange as necessary after consultation with the Editor.

It was voted that the item for printing pages of advertisements in the *Journal of Industrial and Engineering Chemistry* be struck out of the Budget as a contingent item and be referred to the Board of Directors with power.

It was voted that the Board of Directors be requested if possible to submit the Budget each year to the Council by mail in advance of the meeting.

It was voted that the Treasurer be paid a salary of two hundred dollars a year and that this item be added to the Budget.

It was voted that the following Budget as a whole be referred to the

Board of Directors with the recommendation that it be passed by them in conformity with the acts of this meeting.

Budget for 1910.

RECEIPTS.

Dues	$42,000.00
Advertisements	6,500.00
Subscriptions	2,500.00
Postage	500.00
Back numbers	1,000.00
Interest	500.00
	$53,000.00

EXPENDITURES.

Journal American Chemical Society:		
Editor's salary	$ 1,000.00	
Expenses	200.00	
Reviews	100.00	
Printing	7,070.00	
Reprints (net)	350.00	
Total		8,720.00
Chemical Abstracts:		
Editor's salary	$ 1,000.00	
Associate editor, salary	867.00	
Assistance, including indexer	1,583.00	
Expenses	450.00	
Abstractors	4,700.00	
Printing, including index	14,650.00	
Total		23,250.00
Journal of Industrial and Engineering Chemistry:		
Editor salary	$ 1,000.00	
Printing 850 pages at $6.20 per page	5,270.00	
Printing advertisements[1]		
Authors' reprints, $50 per month	600.00	
Index	100.00	
Postage, $20.00 per month	240.00	
Expense	600.00	
Clerical[2]		
Special expense[3]	300.00	
Total		7,810.00
Commission: advertising, at 20 per cent.		1,300.00
collections, at 4 per cent		1,840.00
Secretary's office:		
Clerical		1,200.00
Expense		1,250.00

[1] Referred to directors.

[2] Appropriation covering first six months.

[3] The item of clerical expense has been left to the directors with power. The editor estimates that $60 per month will be required until such time as he is relieved of the advertising and $30 per month thereafter.

Treasurer's office:	
Salary	200.00
Expense	400.00
President's office	50.00
Librarian's office	500.00
General meetings	1,500.00
Local sections	2,500.00
Incidentals	800.00
Back numbers	500.00
Directory	350.00
Total	$52,170.00
Contingent items (noted in foot-notes) estimated 120 pages advertisement Jour. I. & E. C.	744.00
Clerical, Editor of Jour. I. & E. C.	420.00
Grand total	$53,334.00

It was voted that the title of the general Committee on Uniformity of Technical Analysis be changed to the Committee on Standard Methods of Analysis.

It was voted that the Committee on Standard Methods of Technical Analysis of the Division of Industrial Chemists and Chemical Engineers be constituted a subcommittee of the Committee on Standard Methods of Analysis, and that the Chairman of the said Committee of the Division of Industrial Chemists and Chemical Engineers be a member of the general committee with right to vote limited to matters relating to the work of his own committee.

It was voted that all committees similarly constituted to standardize methods of analysis be likewise made subcommittees of the Committee on Standard Methods of Analysis.

The following officers were then elected: *Directors for two years*, A. D. Little, E. G. Love. *Finance Committee*, E. G. Love, P. C. McIlhiney, G. C. Stone. *Membership Committee*, Wm. McMurtrie, E. G. Love, B. E. Curry. *Secretary*, Charles L. Parsons. *Treasurer*, Albert P. Hallock. *Librarian*, Daniel D. Berolzheimer. *Editors*: *Journal of the American Chemical Society*—W. A. Noyes, *Editor-in-Chief*; M. T. Bogert, Edward Hart, W. F. Hillebrand, J. H. Long, Arthur A. Noyes, Charles L. Parsons, H. P. Talbot, H. W. Wiley. *Chemical Abstracts*—A. M. Patterson, *Editor-in-Chief*; J. J. Miller, *Associate Editor*. *Journal of Industrial and Engineering Chemistry*—W. D. Richardson, *Editor-in-Chief*; Geo. P. Adamson, E. G. Bailey, G. E. Barton, Wm. Brady, Wm. Campbell, F. B. Carpenter, Virgil Coblentz, Francis I. Dupont, W. C. Ebaugh, Wm. C. Geer, W. F. Hillebrand, W. D. Horne, L. P. Kinnicutt, A. E. Leach, Karl Langenbeck, A. D. Little, P. C. McIlhiney, E. B. McCready, Wm. McMurtrie, J. Merritt Matthews, T. J. Parker, J. D. Pennock, G. C. Stone, F. W. Traphagen, Ernst Twitchell, Robert Wahl, Wm. H. Walker, M. C. Whitaker, W. R. Whitney.

W. D. Bancroft having been elected President and also Councilor-at-Large, it devolved upon the Council to elect a Councilor in his place and W. L. Dudley, of Nashville, Tenn., was elected Councilor-at-Large for three years from January 10, 1910.

It was voted that the vacancies on the Board of Editors of the *Journal of Industrial and Engineering Chemistry* be referred to the Executive Committee of the Division of Industrial Chemists and Chemical Engineers with power to fill same and that any other vacancies occurring between meetings be likewise treated.

The committee appointed at the previous meeting to consider the publication of papers other than those printed in the Society's Journals reported but after considerable discussion the report, mainly for financial reasons, was tabled.

It was voted unanimously that the Council express its appreciation to Dr. E. G. Love for his long and faithful services as Librarian of the Society.

It was voted the Council express to Dr. Wm. McMurtrie their sincere congratulation on the recovery of his health and the hope that he may soon be able to meet with them again.

It was voted that the Council express their sincere thanks and appreciation to the authorities of the Ohio State University, the University of Illinois and the New Hampshire College for the courtesies which those institutions are extending to the Editor of *Chemical Abstracts*, to the Editor of the *Journal of the American Chemical Society* and to the Secretary.

It was voted that the thanks of the Council be extended to all the officers of the Society who have served them so faithfully during the past year.

It was voted that the Editor of *Chemical Abstracts* be made Chairman of the Committee on Exchanges and that the committee consist of the Editors of the Society's Journals and the Librarian.

It was voted that the Council meetings called at the time of the Annual Meeting of the Society shall begin at 2.30 o'clock on the afternoon preceding the opening session.

Adjourned.

CHARLES L. PARSONS,
Secretary.

MEMBERS ELECTED BETWEEN DEC. 15, 1909, AND JAN. 15, 1910.

Alkier, S. J., 6 Sumner Ave., Brooklyn, N. Y.

BOARD OF DIRECTORS.

A meeting of the Board of Directors was held at the Hotel Lenox at 1.30 A.M., Thursday, December 30th, with Messrs. Whitney, Bogert, Parker, Hallock and Parsons present.

A quorum being announced, it was voted that all the recommendations of the Council with regard to financial matters as recorded in the minutes of the Council for December 27, 1909, and December 29, 1909, are hereby approved and adopted as the action of the Board of Directors.

Adjourned. CHARLES L. PARSONS,
Secretary.

MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons, Durham, N. H.]

PITTSBURG SECTION.

The regular meeting of the Section was held at the Carnegie Technical Schools, Applied Science Building, on Thursday evening, December 16th, at 8 o'clock.

The program included the following papers: "Some Improved Gas Analysis Apparatus," by Dr. E. J. Hoffman, U. S. Geol. Survey. "The Determination of the Percentage of Phosphorus Retained with the Ferric Chloride in the Ether Separation," by R. J. Wysor, Chemist, Carnegie Steel Co. "The Analysis of Explosives," by Dr. Walter O. Snelling, U. S. Geol. Survey. JOHN A. SCHAEFFER, *Secretary.*

SECTION OF EASTERN NEW YORK.

The October meeting was held at Schenectady on Friday, October 15, 1909, at 8 P.M., in the parlors of the New Vendome Hotel. Dr. M. A. Hunter spoke on the subject "The Natural Resources of New Zealand," relating some observations of his recent trip to the Southern Pacific.

The December meeting was held at the Rensselaer Polytechnic Institute, Troy, on Friday evening, December 17, 1909, at 8 o'clock. Dr. A. T. Lincoln gave a paper on "The Hydrate Theory of Solutions."

The Troy ladies served refreshments at the close of the program.

The following officers were elected for 1910: *President*, Edward Ellery, Union Univ., Schenectady; *Vice-President*, John Hurley, Little Falls, N. Y.; *Secretary-Treasurer*, R. C. Robinson, Res. Lab., G. E. Co.; *Councilor*, M. A. Hunter, R. P. I., Troy *Advisory Committee*, A. T. Lincoln, R. P. I., Troy; W. R. Whitney, Schenectady; F. C. Zapf, 335 McClellan St., Schenectady.

F. C. ZAPF, *Retiring Secretary.*

The January meeting was held in the Chemical Lecture Room of Union College, on Friday evening, January 7th, at 8 o'clock.

Dr. C. F. Hale, of the Research Laboratory of the General Electric Co., gave a paper on "Recent Advances in the Liquefaction of Gases," illustrated with lantern slides and experiments.

Business meeting and refreshments followed.

R. C. ROBINSON, *Secretary.*

WISCONSIN SECTION.

At the annual meeting of the Section held December 8, 1909, the following officers were elected for the year 1910: *Chairman,* E. B. Hart; *Vice-Chairman,* Richard Fischer; *Councilor,* H. C. Bradley; *Secretary,* E. V. McCollum; *Treasurer,* W. F. Koelker.

FRANCIS C. KRAUSKOPF, *Retiring Secretary.*

The January meeting was held at Madison on Wednesday, January 12th, at 8 P.M. in the Chemistry Building Professor W. F. Koelker presented a paper on "The Utilization of the Amino Acids and Polypeptids by the Tubercle Bacillus."

Following the paper there was an informal discussion of the Boston Meeting of the Chemical Society by Professors Kahlenberg, Bradley and Loevenhart.

E. V. MCCOLLUM. *Secretary.*

INDIANA SECTION.

The Section met Friday evening, December 10, 1909, at 7.15 o'clock, at the office of the State Food and Drug Laboratory. The following papers were read: "Concerning the Decomposition of Uric Acid by Enzymes," Clarence E. May; "Boiler Water in Railway Service," J. R. Francis; "Scientific Treatment of the Problem of Cutting a Brilliant of Any Transparent Material," F. B. Wade; "Morphine Determinations," A. D. Thorburn.

A. D. THORBURN, *Secretary.*

IOWA SECTION.

The December meeting was held in Iowa City on December 11, 1909. The forenoon was given over to the reading of papers and discussions. After a dinner at the Burkeley Imperial, the meeting adjourned to inspect the plant for the electrolytic bleaching of flour recently installed in a local flour mill. The following papers were presented: "The Estimation of Cobalt and Arsenic in Smaltite," Nicholas Knight. "Nitrogenous Excretion," Miss Stella Hartzell. "Metallic Tellurites," Edward Wolesensky. "Delicate Tests for Cobalt in the Presence of Nickel and Iron," W. J. Karslake. "Colloidal Solutions," J. N. Pearce. "Bleaching of Flour," E. W. Rockwood.

J. NEWTON PEARCE, *Secretary.*

ST. LOUIS SECTION.

The regular monthly meeting was held on Monday evening, December 13th, at the Academy of Science Building. The following were elected officers for the year 1910: *President*, Prof. Edward H. Keiser; *Vice-President*, Dr. Charles E. Caspari; *Secretary*, Mr. R. Norris Shreve; *Treasurer*, Dr. Samuel H. Baer; *Councilor*, Mr. H. E. Wiedemann.

Mr. H. E. Wiedemann read a paper on "The Relation of Chemistry and Chemical Engineering to the Conservation of Our Natural Resources."

LEROY MCMASTER, *Retiring Secretary.*

The St. Louis Section met in conjunction with the St. Louis Chemical Society on January 10th. Messrs Alfred L. Kammerer and E. B. Fulks read a paper on "Timber Preservation." This paper, in the nature of a review of the work done by the railroads on this subject, was well illustrated by lantern slides. Mr. H. E. Wiedemann gave a résumé of the Boston meeting of the general society.

R. NORRIS SHREVE, *Secretary.*

LOUISIANA SECTION.

The thirty-sixth regular meeting was held on Friday evening, December 17th, in the Director's Room of the New Orleans Board of Trade. President F. C. Johnson presided. Dr. J. C. Mims presented a paper on "Waste Products." The usual discussion followed the reading of the paper and brought out some very interesting facts in regard to local trade problems.

W. L. HOWELL, *Secretary.*

NEW YORK SECTION.

The third regular meeting of the Session of 1909-'10 was held at the Chemists' Club, on Friday evening, December 17th. The following members were elected Councilors for the ensuing year: Morris Loeb, E. G. Love, Geo. C. Stone, L. H. Baekeland, T. J. Parker, W. D. Horne, Chas. Baskerville. The papers read were as follows: "Analyses of Some Antique Bronzes," Morris Loeb and L. R. Morey. "The Action of Radium Salts upon Ruby," Chas. Baskerville. "Apparatus for Drying Flasks," Chas. Baskerville and Reston Stevenson.

The fourth regular meeting of the Session of 1909-'10 was held at the Chemists' Club on January 7th. The program was as follows: "The Origin of the Chemical Elements," Henry B. Russell. "Chemical Examination of Watermelon Seed," and "Chemical Examination of Pumpkin Seed," F. B. Power and A. H. Salway. "Further Researches in the Quinazoline Field," C. G. Amend and M. T. Bogert.

C. M. JOYCE, *Secretary.*

UNIVERSITY OF ILLINOIS SECTION.

The regular December meeting was held at the Chemistry Building, December 21, 1909. The following papers were presented: "The Heat of Solutions of Metals in Acids," Dr. L. L. Burgess. "The Effect of

External Conditions upon the Physiological Activities of Some De-nitrifying Organisms." Dr. J. H. Petit.

L. H. SMITH, *Secretary.*

SYRACUSE SECTION.

The 54th regular meeting was held Friday evening, December 17th, at 8 P.M., in the Lecture Room of the Y. M. C. A.

The papers presented were as follows: "Invertase," by C. S. Hudson, Washington, D. C. "Some New Electrochemical Processes," by E. H. Archibald. "An Electric Gas Meter," by E. C. Scott. "Report of the Recent Convention of Chemical Engineers," by W. M. Booth.

The fifty-fifth regular meeting was held Friday evening, January 7, 1910, at 8 P.M. in Bowne Hall, Syracuse University. Professor Julius Stieglitz, from the University of Chicago, delivered an experimental lecture on "The Electrical Theory of Oxidation and Reduction."

An informal dinner was served at Sims Hall, Friday at 6.30 P.M., just preceding the lecture.

WM. H. MCLAUCHLAN, *Secretary.*

CINCINNATI SECTION.

At the December meeting of our Section Mr. Jerome K. Alexander, of New York City, addressed the members on the Ultra-microscope and demonstrated its use.

The 156th meeting of the Section was held on Wednesday evening, January 12th, at 8 o'clock, in the Chemical Lecture Room of the Ohio Mechanics Institute. An address entitled "Chemical Theories" was delivered by Mr. Joseph Ellms.

Reports of the Boston Meeting were made by Prof. H. S. Fry, Dr. E. Reemelin and Dr. Alfred Springer.

ALFRED SMITH, *Recording Secretary.*

WASHINGTON SECTION.

The 195th meeting was held Thursday, January 13, 1910, at 8 P.M., in the Chemical Lecture Room of George Washington University. The following program was presented: "Nitrification in Soils," K. F. Kellerman, E. R. Allen and I. G. McBeth (B. P. I.). "Availability of Iodophenin in the Separation of Acetanilid and Acetphenetidin," W. O. Emery (Bur. Chem.). "Translocation of Plant Food during Germination of Wheat," J. F. Breazeale (Bur. Chem.).

J. A. LECLERC, *Secretary.*

DECEASED MEMBERS.

John D. Billings, Syracuse, N. Y.
Charles B. Dudley, December 21, 1909, Altoona, Pa.
Ottokar Hofmann, December 24, 1909, Kansas City, Mo.
W. A. Syme, Raleigh, No. Car.

Charles Benjamin Dudley.

In the death of Dr. Charles B. Dudley, which occurred on December 21, 1909, at his home at Altoona, Pa., the result of a brief and unusually severe attack of pneumonia, the *American Chemical Society* has lost one of its most valued members, whether measured by the duration of his connection with the Society, the wisdom and helpfulness of his counsel, or his loyalty to its interests; chemical science has lost one of its most able exponents; and the country a most patriotic and useful citizen.

Dr. Dudley was the son of Daniel and Miranda Bemis Dudley, both of New England origin, and was born at Oxford, N. Y., July 14, 1842. His boyhood appears to have been such as was then typical of the intelligent country lad and was made up mainly of attendance upon the local school and academy, and work upon the farm, with such recreations as village life afforded. He found in this experience incentive for further study, and had commenced his preparation for college when the Civil War broke out, and he determined to enlist in the One Hundred and Fourteenth Regiment of New York Volunteers in 1862. During the period of his enlistment he took part in seven battles and was severely wounded in the leg on September 19, 1864 at Opequan Creek, which resulted in a permanent lameness. During his military service he devoted a portion of his time to study, and on his return to his home in 1865, he renewed his preparation for college at Oxford Academy and Collegiate Institute, subsequently entering and graduating from Yale College with the degree of A. B. in 1871. A year of work upon a newspaper at New Haven was followed by two years of study along chemical lines at the Sheffield Scientific School, and the award of the degree of doctor of philosophy in 1874, and this, in turn, by a year as assistant to Professor George F. Barker in the department of physics of the University of Pennsylvania. A prospective period of service as teacher of science at Riverview Military Academy, Poughkeepsie, N. Y., was interrupted at the end of a month by his acceptance, November 10, 1875, of the position of chemist for the Pennsylvania Railroad Company at Altoona, Pa., a position which (with the title changed to that of chief chemist) he held at the time of his death. He was married on April 17, 1906, to Mary V. Crawford, who survives him.

Dr. Dudley was a charter member of the American Chemical Society, for many years a member of its Council and Board of Directors, and President of the Society from 1896 to 1898. He had been President of the American Society for Testing Materials since 1902 and at the time of his death was also President of the International Association for Testing Materials. He was also President of the Bureau for Safe Transportation of Explosives of the American Railway Association, and a member of a large number of the national societies, including those of civil, mining, mechanical, electrical and sanitary engineering, as well as the Washington Academy of Science, The American Historical Society, The American Philosophical Society, and the Iron and Steel Institute of Great Britain, and other foreign societies. His club membership included the Union League of Philadelphia, The Cosmos Club of Washington, The Chemists' Club and the Engineers' Club of New York.

The mere outline of Dr. Dudley's life and affiliations is itself an index of the catholicity of his interests and the wide range of his activities. During the thirty-four years of his service as chemist of the Pennsylvania Railroad Company he was instrumental in building up their system of tests from its beginning in 1875, when a few hundred dollars' worth of material only was reported upon, to the present elaborate and efficient system of purchase under specification and the series of testing laboratories, not only in chemistry but in allied sciences, which either came under his supervision or for which his advice was often sought. These laboratories now pass upon nearly as many million dollars' worth each year as hundreds of dollars' worth in 1876. The influence of this work upon the interests and welfare of The Pennsylvania Railroad itself, great as it has been, is but a part of the results of Dr. Dudley's life work; for, from this work may be said to have grown the previously unknown but new general practice of formulation of specifications for the purchase and testing of materials, which has been of such incalculable benefit to commercial interests of all kinds. Dr. Dudley's commanding influence was attained in part through his publication of carefully developed analytical procedures in the scientific journals and in the specifications of the Railroad Company; in part, through recognition of his exhaustive and painstaking study of structural materials, notably irons and steels, with reference to durability and possible improvements, the results of which nearly revolutionized railroad construction; but probably mainly through his strong, sane addresses delivered before various scientific organizations, and particularly through his services as president of the American Society for Testing Materials. No one who has heard his noteworthy presidential addresses could doubt that the success of that Society has been very largely due to the energy and enthusiasm which he devoted to it. His election to the presidency of the International Association was a deserved tribute to his efficient service. In considering his successes one should, moreover, not lose sight of the influence of his character, which combined the mind of the thoughtful, careful student, with sound judgment in practical affairs, and a remarkably keen sense of equity, all these traits being further combined with a uniform good nature which went far to enable Dr. Dudley to bring men of initially widely divergent opinions to a common understanding.

Dr. Dudley's life was unique in its breadth of scientific experiences and in the variety of questions upon which it was necessary to express an intelligent opinion and of problems for which a solution was demanded. His pioneer work on irons and steels, which gave him a position of authority with both manufacturers and consumers, and his extended contributions to chemical analysis referred to above are two of the important phases of his scientific achievements. His study of the chemistry and physics of the bronzes and bearing metals resulted more or less directly in the modification of the construction of journals, with a marked increase of bearing surface, which was doubtless a factor in the development of the present high-capacity freight car and probably of other modern forms of rolling stock as well. A careful study of the ventilation of passenger cars, and the ventilation and disinfection of sleeping cars was made under his direction. His widely recognized standing as an authority upon matters relating to the transportation of explosives and other hazardous materials was the outcome of many years of study and experimentation which he himself regarded as a most important part of his scientific work, and his advice regarding these matters was constantly sought.

These are but a very few of the lines along which he thought and worked, which come readily to mind. Of the almost countless individual problems which he met, and often solved, no one could write save Dr. Dudley himself, and it is indeed unfortunate that the exigencies of his busy life prevented him from carrying out his expressed intention to give permanent form to a record of activities which would have possessed much more than ordinary interest and value. But Dr. Dudley was a tireless worker, and was so often called upon to assume new responsibilities that it would not be strange if the load had become heavier than even he could properly hope to carry. He always, however, gave freely of his time, energy, and counsel to worthy causes. His services to this Society are a token of this, and these will be gratefully recalled by many members, especially those familiar with the stressful days of the earlier years of the Society's existence.

His interest in his fellow men is also conspicuously demonstrated in his work for the Altoona Mechanics' Library, which is largely the product of his efforts.

Dr. Dudley's name will stand among American chemists as an example of the scholarly, broad-minded, tireless worker, modest yet courageous and tactful, who contributed to applied chemistry in its largest sense and in a measure which it is yet impossible to estimate. His friends will retain many memories of delightful companionship, quick sympathy with joy or sorrow, helpful counsel in perplexity, and unselfish service in time of need.

H. P. TALBOT.

Issued with the March Number, 1910.

Proceedings.

COUNCIL.

Ex-President Whitney, according to the vote at the Boston meeting, has after consultation with the Executive Committee of the Division of Agricultural and Food Chemistry, appointed H. J. Wheeler, Chairman, J. H. Long, Wm. McPherson, H. C. Sherman, F. T. Shutt, Alfred Springer, A. L. Winton and L. L. Van Slyke a committee to consider the question of the publication of a Journal of Agricultural and Food Chemistry.

President Bancroft has appointed G. C. Stone and H. P. Talbot members of the Committee on Standard Methods of Analysis, of which W. F. Hillebrand is Chairman. CHARLES L. PARSONS, *Secretary.*

MEMBERS ELECTED BETWEEN JANUARY 15TH AND FEBRUARY 15TH.

Abbott, Wm. G., Jr., 54 Park St., Lynn, Mass.

MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons, Durham, N. H.]

PUGET SOUND SECTION.

The fifth meeting of the Section was held at the Butler Hotel Annex, Saturday, December 4th, at 6.30 P.M. After dinner, the following program was enjoyed: "Some Non-Ionic Reactions," by Dr. W. M. Dehn. "The Status of Powdered Coal as a Fuel," by Dwight C. Farnham.

A. JACOBSON, *Secretary*.

CHICAGO SECTION.

The December meeting was held at the Kimball Café, on Friday evening, December 17th. The program for the evening was "The Council on Pharmacy and Chemistry and the Chemical Laboratory of the American Medical Association," by W. A. Puckner, Secretary, Council on Pharmacy and Chemistry, A. M. A.

After the lecture the following officers were elected for 1910: T. J. Bryan, *Chairman*; H. McCormack, *Vice-Chairman*; A. Lowenstein, *Treasurer*; A. L. Nehls, 4652 Malden St., *Secretary*; W. R. Smith, William Brady, J. Stieglitz, *Councilors*; additional member executive committee, I. M. Bregowski.

The January meeting was held January 28th, at the Kimball Café. The usual dinner preceded the meeting.

Mr. Converse, the retiring chairman, offered to present a medal for the best paper delivered before the Chicago Section during each year, the exact conditions of award and design to be left to a committee appointed by the Section. The committee will report at the February meeting.

W. D. Richardson gave a paper on "The Electrolytic Theory of Corrosion and an Amendment Thereto."

Mrs. Wm. Brady read a paper on "The Entertainment of Ladies at the Boston Meeting," which was one of the most enjoyable papers ever presented before the Section. W. R. Smith reported on the Boston meeting.

A. L. NEHLS, *Secretary*.

NORTH CAROLINA SECTION.

The midwinter meeting of the Section was held Friday, January 14th, at 8 P.M., in the Agricultural Building at Raleigh.

Officers for 1910 were elected as follows: *President*, W. M. Allen; *Vice-President*, Daisy B. Allen; *Secretary-Treasurer*, B. J. Ray; *Councilor*, J. E. Mills; *Reporters*, Manlius Orr, Duncan MacRae.

The following program was presented: "Chemistry of Commercial Feeds," by G. M. MacNider. "The Determination of Flaxseed Products by the Specific Gravity Method," by C. H. Herty and E. J. Newell.

"Caffeine in Our Beverages," by E. V. Howell. "A Comparison of the Foster, the Tagliabue and the New York Board of Health Oil Testers," by Manlius Orr. "Application of Physical Chemistry to the Study of the Oleo-Resins," by C. H. Herty. "Bromination of Anthranilic Acid," by A. S. Wheeler and W. M. Oates. "Nature of Attractive Forces," by J. E. Mills. "The Delicacy of the Diphenylamine Test for Nitrates and Nitrites," by W. A. Withers and B. J. Ray. Account of the Boston meeting was given by J. E. Mills.

BURTON J. RAY, *Secretary.*

CORNELL SECTION.

The 58th regular meeting of the Section was held in Morse Hall, Cornell Univ., Friday, January 14, 1910.

The program presented was as follows: "Further Contributions to the Chemistry of the Phenolsulphonic Acid Method for Nitrates," by D. S. Pratt. "Ammonolysis of Hydrazine Sulphate," by T. W. B. Welsh. "Electrolytic Corrosion of Some Metals," by G. R. White. "The Influence of the Basicity of the Soil and of the Growth of Legumes on the Availability of Soil Nitrogen," by Dr. T. L. Lyon. "Report of the Boston Meeting," by Prof. A. W. Browne.

H. W. GILLETT, *Secretary.*

KANSAS CITY SECTION.

The January meeting of the Section was held at the Y. M. C. A. Building, Tenth and Oak St., Kansas City, Saturday evening, January 15th, at 5 o'clock.

The program began with a paper by Mr. Rudolph Hirsch, on the "Food Law and the Jobber." After dinner Prof. H. Louis Jackson read a paper on the "Food Law and the State," followed by a discussion by A. V. H. Mory and Messrs. Bailey, Willard, Sayre and Crumbine.

E A. WHITE, *Secretary.*

UNIVERSITY OF ILLINOIS SECTION.

The regular meeting of the Section was held January 18th at the Chemistry Building, Urbana, Illinois.

The following topics were presented: "Atomic Weight of Phosphorus," by Dr. Grinnell Jones. "Adiabatic Determination of Heat of Combustion," by Dr. R. H. Jesse, Jr.

The February meeting was held Tuesday, February 15th, at 7.30 o'clock, at the Chemistry Building. The following topics were presented: "The Atomic Weight of Tantalum," by Dr. C. W. Balke. "A Measure of Thermodynamic Positivity and Negativity," by C. G. Derick.

L. H. SMITH, *Secretary.*

PITTSBURG SECTION.

The regular meeting of the Section was held in the new Engineering

Building of the University of Pittsburg, on Thursday evening, January 20th.

The program of the evening was: The Boston Meeting—Brief reports on its most interesting features by Messrs. Porter, Handy, Mason, Phillips, Clement, Allen and Chamberlain. "The Manufacture and Analysis of Smokeless Powder"—Mr. C. G. Storm.

The February meeting was held in the assembly room of the Carnegie Technical Schools, on Thursday evening, February 17th.

The following address was given: "Results of Laboratory and Field Inspection of Various Painting Tests," by Henry A. Gardner, Director of the Scientific Section, Paint Manufacturers' Association of the United States.

JOHN A SCHAEFFER, *Secretary.*

PHILADELPHIA SECTION.

The regular meeting of the Section was held at the Engineers' Club, Philadelphia, Thursday evening, January 20th.

The following program was presented:

Report of the Councilors who attended the Boston meeting of the American Chemical Society.

Papers: "The Cause of Color in Plants," by Henrv Kraemer. "The Extraction of Gold from Sea Water," by Arthur W. Comey. "Is There Caramelization in Riva's Test?" by D. W. Horn.

The February meeting was held at the Engineers' Club, Thursday evening, February 17th.

Two papers were presented as follows: "The Application of the Jet in Chemical Processes," by Dr. Oskar Nagel. "The Chemistry of the Tariff of 1909," by C. C. Roberts. The usual informal dinner was served before the meetings.

F E. DODGE, *Secretary.*

RHODE ISLAND SECTION.

The regular meeting of the Section was held January 20th, at the University Club, Providence, and was preceded by the usual informal dinner.

The paper for the evening was by Dr. John E. Bucher, of Brown University, on "The Structure of Retene and Its Relation to Some Natural Resins." Dr. Bucher showed conclusively that the correct structure of retene is 8-methyl-2-isopropylphenanthrene and not the formula ordinarily published in the literature.

ALBERT W CLAFLIN, *Secretary.*

LOUISIANA SECTION.

The thirty-seventh regular meeting of the Section was held January

21st. A very interesting paper was read by L. A. Becnel on "The Causes of Variations in Sugar House Results."

The following officers were elected to serve for the ensuing year: *President,* Dr. Philip Asher; *Vice-President,* Mr. L. A. Becnel; *Secretary-Treasurer,* Mr. George B. Taylor; *Councilor,* Dr. C. E. Coates; *Executive Committee,* Dr. B. P. Caldwell, Mr. F. C. Johnson, Mr. H. Z. E. Perkins.

GEORGE B. TAYLOR, *Secretary.*

NORTHEASTERN SECTION.

The ninety-sixth regular meeting of the Section was held on January 21st, at the Twentieth Century Club, Boston. It was voted that alternate bi-monthly meetings be held jointly with the New England Section of the Society of Chemical Industry.

Professor Louis Derr, of the Massachusetts Institute of Technology, presented a paper entitled "Color Photography at the Present Time." The lecture was profusely illustrated with very beautiful and striking examples of color photography, including some most remarkable results with brilliant micro-photographs.

K. L. MARK, *Secretary.*

UNIVERSITY OF MISSOURI SECTION.

The sixth regular meeting of the Section was held on Friday evening, January 21st. Mr. C. K. Francis delivered the paper of the evening on the "Glycogen Content of Beef Flesh." Mr. E. A. Perkins gave a short note describing an "Apparatus for Measuring the Comparative Hardness of Fat or Similar Substances."

C. ROBERT MOULTON, *Secretary.*

MILWAUKEE SECTION.

The regular meeting of the Section was held at Milwaukee Public Museum, Friday evening, January 28th.

Two papers was presented as follows: "Iron and Steel," by R. S. MacPherran, Chemist, Allis-Chalmers Co. "Lead Smelting," by B. L. Salomon, Asst. Chemist, C. M. & St. P. Ry.

H. M. SOPER, *Secretary.*

CALIFORNIA SECTION.

The forty-ninth regular meeting of the Section was held on Saturday evening, January 29th, in the College Room of the Bismarck Café, San Francisco.

Dr. E. C. Franklin presented a paper on "The Bearing of Recent Work in Radioactivity on the Atomic Theory."

CHARLES ASH, *Secretary.*

LOUISVILLE SECTION.

The February meeting of the Section was held at the Seelbach Hotel on the 7th at 8 P.M. The regular program was changed somewhat by having four short discussions instead of one paper. Much interest was taken by those present.

The following subjects were presented: "Reducing Oils for Paints," by R. C. Lord. "The Detection of Alumina in Water," by W. H. Lovejoy. "The Purchase of Coal on the B. T. U. Basis," by A. M. Breckler. "Gravimetric Determination of Reducing Sugars," by F. F. Hasbrouck. The usual lunch followed in the Rathskellar. F. F. HASBROUCK, *Secretary.*

CINCINNATI SECTION.

The 157th meeting of the Section was held on Wednesday evening, February 9th, in the Ohio Mechanics Institute.

Two addresses were presented: "The Interpretation and Value of Physical and Chemical Tests in the Control of Water Purification Plants," by Mr. Clarence Bahlmann. "The Biological Features of Water Purification at Cincinnati, Ohio," by Mr. L. G. Gedesche.

ALFRED SMITH, *Recording Secretary.*

WASHINGTON SECTION.

The one hundred ninety-sixth meeting, on Thursday, February 10th, 8 P.M., was held at the Public Library Lecture Hall.

The following program was presented: "Solubility of Gold in Nitric Acid," by F. P. Dewey. "The Detection of the Deterioration of Corn with Special Reference to Pellagra," by C. L. Alsberg and O. F. Black (B. P. I.)

Presentation of Notes, Exhibition of Apparatus, etc.

J. A. LECLERC, *Secretary.*

WISCONSIN SECTION.

The regular meeting of the Section was held at Madison on Thursday, February 10th, at 8 P.M., in the Chemistry Building.

Professor J. L. Sammis presented a paper on "The Separation of Curd from Butter Milk," and Dr. S. M. Babcock presented a paper on "The Importance of Metabolic Water in the Development of Living Organisms."

E. V McCOLLUM, *Secretary.*

NEW YORK SECTION.

The fifth regular meeting of the Session of 1909–'10 was held at the Chemists' Club on Friday, February 11th.

The following papers were presented: "Nucleic Acids," by P. A. Levene. "Determination of Sodium Chloride in Milk," by Paul Poetschke. "Some Colloid-chemical Aspects of Digestion, with Ultra-microscopic Observations," Jerome Alexander. "The Fate of Amino Acids in the Organism," by Graham Lusk. C. M. JOYCE, *Secretary.*

SYRACUSE SECTION.

The fifty-sixth meeting was held as a smoker on Friday, February 11th, 8 P.M.

The following program was presented: "The Chemist and the Community," by A. D. Little, reviewed by M. R. Bradway. "The Conference of the Sections," by President H. C. Cooper. "The Chemist's Place in Industry," by A. D. Little, read by Myron Allen.

WM. H. MCLAUCHLAN, *Secretary.*

SECTION OF EASTERN NEW YORK.

The February meeting was held in the Union College Chapel, Schenectady, on Friday evening, February 18th.

The following paper illustrated by lantern slides was presented: "Modern Bacterial Methods of Sewage Treatment," by Prof. L. P. Kinnicutt.

R. C. ROBINSON, *Secretary.*

MINNESOTA LOCAL SECTION.

The regular meeting of the Section was held Friday evening, January 14th, at 8 P.M., in the Chemical Laboratory of the University. An important business meeting to formulate plans for the entertainment of the National Society at its next winter meeting in Minneapolis was followed by a report on meetings of the Council, and of the Industrial and Organic Divisions at Boston, by G. B. Frankforter, and a report on the Inorganic and Physical Division and the Vice-Presidential address by W. H. Hunter.

FRANCIS C. FRARY, *Secretary.*

DECEASED MEMBER.

Dr. August G. Seher, 110 Montclair Ave., Newark, N. J., died October 7, 1909.

Charles Benjamin Dudley.

Obiit December 21, 1909.

Well have you done the labors of a life
Of service for your country and for God,
Whether the paths of flaming fields you trod
In battle for the Nation rent with strife
Where cannon's thunder smothered drum and fife,
Or following the plow across the sod,
Or tarrying where sons of science plod—
A fount of cheer for comrade, friend and wife.
The ripple of your laugh, the clear sweet light
Of those dear eyes forever closed to earth
Shall glad and guide me as I near the night
Now closing on my day of deeds and mirth,
Its glowing glory waxing ever bright
In th'unfathom'd shadows of the second birth.

HARVEY W. WILEY.

San Francisco Meeting.

The Forty-second General Meeting of the American Chemical Society will be held in San Francisco, California, July 12 to 15, 1910.

The California Section is planning to make this meeting one of the most enjoyable ever held, and it is hoped that a large delegation from the East will attend. We shall have advantage of the lowest convention rate ever given, *viz.*, $62.50 from Chicago and return, with return ticket good until October 31st and departure between July 3rd and 8th. A choice of routes will be allowed coming home with $15.00 additional if the Northern Route *via* Portland, Oregon, is chosen. Special rates from the East to Chicago are also expected.

A cordial invitation has been received from the Puget Sound Section for the members to stop at Seattle as the guests of that Section either going to or coming from the San Francisco Meeting. It is hoped that some arrangement to accomplish this can be made.

A special train from Chicago is offered if one hundred tickets are guaranteed in advance. This train will have all the features of the highest class service of the Western roads. Arrangements will be made for stop-overs and sight-seeing en route. If the Southern route is chosen, stops may be made at Colorado Springs, Grand Cañon, one of the Indian Pueblos, etc. If the train goes *via* Salt Lake City, arrangements may be made to visit the large smelters near-by.

Members are urged to communicate with the Secretary at once in regard to their choice of route, and their intention to be present so that plans may be formulated to please all. We feel practically sure of the special train in which all can go together and enjoy one of the finest outings of our lives. To insure its success, however, it is essential that you do your part by informing me at the earliest possible moment of your intention to be with us.

Every comfort will be provided for ladies. *Reservations for the special train will be given precedence in the order of their receipt.*

CHARLES L. PARSONS, *Secretary.*

Proceedings.*

COUNCIL.

MEMBERS ELECTED BETWEEN FEBRUARY 15TH AND MARCH 15TH.

Almy, Charles, Jr., 147 Brattle St., Cambridge, Mass.
Andrews, Arthur B., 32 High St., Auburn, Maine.
Anthony, Stephen, College of Agriculture, St. Anthony Park, Minn.
Baker, R. E., 611 E. Franklin Ave., Minneapolis, Minn.
Barr, Richard S., Mansfield, Ohio.
Bashore, E. G., care of Babcock & Wilcox Co., Bayonne, N. J.
Bates, John S., Hartley Hall, Columbia Univ., New York City.
Berndt, Albert C., 532 Sims Hall, Syracuse, N. Y.
Blackie, Archibald, 223 James St., Winnipeg, Canada.
Boyle, Jas. J., Box 293, Ambridge, Penna.
Brooks, William Conrad, 540 Lincoln St., Bloomington, Ind.
Buchan, Dean W., 257 Byron St., Palo Alto, Calif.
Cameron, Jasper, 2025 Iowa St., Chicago, Ill.
Caskey, Gardner L., care of Navy Dept., Washington, D. C.
Clayton, Robert E., Hanover, Mass.
Corson, Harry P., Durham, New Hampshire.
Edgar, Arthur, 8 St. James Ave , Boston, Mass.
Emery, Albert G., 49 Fenwood Road, Roxbury, Mass.
Faben, Charles R., care of Washington Gas Co., Washington, D. C.
Fegley, John T., 1602 St. Paul St., Baltimore, Md.
Ferriz, Abraham, Dinamita, Durango, Mexico.
Forster, E. L. S., 359 Cooper St., Ottawa, Canada.
Goodwin, J. G., Girard College, Philadelphia, Penna.
Graben, Howard T., 727 E. Congress St., Detroit, Mich.
Graham, H. C., Provincial Lab'y, Edmonton, Alberta, Canada.
Gunning, D. T., 1620 Manhattan Building, Chicago, Ill.
Haines, Drexel W., 77 Van Buren St., Freeport, Ill.
Haskins, Howard D., 1674 E. 93d St., Cleveland, Ohio.
Haynes, Elwood, Kokomo, Ind.
Henry, Arthur G., care of Link Belt Co., Chicago, Ill.
Hicks, John F. G., 517 So. 42d St., Philadelphia, Penna.
Higgins, Harold L., 23 Cumberland St., Boston, Mass.
Holmes, Roy M., 346 Michigan Ave., South Bend, Ind.
Isham, Robert M., 409 E. 14th St., University Place, Nebr.
Jenkins, David E., Cement, Calif.
Jewett, Walter K., University of Nebraska, Lincoln, Nebr.
Keyes, Frederick G., R. I. Hall, Brown Univ., Providence, R. I.
Kubota, Onro, The 7th High School, Kogoshima, Japan.
Larkin, E. H., 109 St. George St., St. Louis, Mo.
Lehmann, Carl, Jarvis St. Collegiate, Toronto, Canada.
Linville, Clarence P., 406 So. Allen St., State College, Penna.
Long, B. E., care of Mercedita Sugar Co., Cabanes, Cuba.
Martin, L. B., 1418 W. St., Washington, D. C.
Oenslager, George, 92 N. Forge St., Akron, Ohio.

Olson, Karl E., 1710 Summit St., Kansas City, Mo.
Osborne, Charles G., 607 Rush St., Chicago, Ill.
Rothwell, T. E., Provincial Assay Office, Belleville, Ont., Canada.
Rouse, B. Irving, 981 Lake Ave., Rochester, N. Y.
Runey, Chas. F., care of Cudahy Packing Co., Kansas City, Kans.
Scott, William C. 420 Tyler St., Sandusky, Ohio.
Sultan, Fred W., 112 N. Second St., St. Louis, Mo.
Thomson, Stuart, 1 State St., Schenectady, N. Y.
Villavecchia, Vittorio, Laboratorio Chimico Centrale, Piazza Mastai, Rome, Italy.
Weed, Robert C., 65 Charles Field St., Providence, R. I.
Werner, A., Chem. Universitäts Laboratorium, Zurich, Switzerland.
Woodrow, John, 84 Harpenden Road, So. Wanstead, Essex, England.
Yard, A. Townsend, 222 Greenwood Ave., Trenton, N. J.
Young, J. Ulric, Tarkio, Mo.
Zieske, Frederick T., 1845 E. 93d St., Chicago, Ill.

MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons, Durham, N. H.]

UNIVERSITY OF ILLINOIS SECTION.

The section was fortunate in securing H. S. Miner, chief chemist for the Welsbach Company, for a lecture on the "Application of the Rare Earths to Incandescent Lighting" on Saturday, January 29th. The lecture was well attended and received with great interest. It was illustrated by use of lantern slides and other demonstrations.

The 29th regular meeting of the Section occurred February 9th, at which time the following papers were presented: "The Atomic Weight of Tantalum," by Dr. C. W. Balke. "A Measure of Thermodynamic Negativity and Positivity," by C. G. Derick.

The regular March meeting occurred Tuesday, March 15th, at 7.30 o'clock at the Chemistry Building.

The following papers were presented: "Equilibrium between Amalgam and Amalgam Solutions," by Dr. Geo. McP. Smith. "The Alkylation of Cyanacetic Ether," by Dr. John C. Hessler. "Opalescence and the Function of Boron in the Glaze," by Mr. R. T. Stull.

L. H. SMITH, *Secretary.*

INDIANA SECTION.

The following papers were read at the meeting of the Section, Friday evening, January 14th, at 7.15 P.M.: "A Simple Method for Determining the Relative Strength of Acids and the Relative Strength of Bases," by W. M. Blanchard, DePauw University. "Some Problems in Iron Analysis," by H. A. Schwartz, Indianapolis.

Supper preceded the meeting.

H. S. Miner, chief chemist of the Welsbach Company, addressed the

Section on "The Rare Earths and Their Use in Incandescent Gas Mantles," at a special meeting held Friday, January 28th, at Shortridge High School.

The following papers were presented at the meeting of the Indiana Section, held at 7.30 o'clock, Friday evening, February 11th, in the office of the State Food and Drug Laboratory: "Laboratory Notes," by Hans A. Duden. "Laboratory Kinks," by R. P. Noble.

On Friday evening, February 18th, the Section gave a dinner at the Columbia Club, Indianapolis. President Stone, of Purdue University, was the speaker.

A. D. THORBURN, *Secretary.*

PUGET SOUND SECTION.

The sixth regular meeting of the Section was held at the "Faculty Club House," University of Washington, Saturday, February 5th, at 8 P.M.

The paper of the evening was on "Conservation and Utilization in the Pacific Northwest," by Dr. H. K. Benson.

The following were elected officers for 1910: *Chairman*, M. J. Falkenburg; *Vice-Chairman*, J. K. Moore; *Councilor*, Dr. H. G. Byers; *Treasurer*, F. F. Flanders; *Secretary*, A. Jacobson.

A special meeting of the Section was held at the Seattle Commercial Club, Thursday evening, Feb. 24th, at 6 o'clock.

After dinner, Dr. R. B. Dole, ass't chemist of The United States Geological Survey, addressed the Section on the "Mineralization of Some American Waters." The address was illustrated with lantern slides.

A. JACOBSON, *Secretary.*

ST. LOUIS SECTION.

The February meeting was held on Monday evening, February 14th, at the Academy of Science Building.

The papers of the evening were: "The Action of Magnesium upon the Vapors of Organic Compounds," by Dr. E. H. Keiser. "The Extraction of Glycerine from Soap Lye," by Mr. Clarence B. Cluff.

R. NORRIS SHREVE, *Secretary.*

LOUISIANA SECTION.

The thirty-eighth regular meeting of the Section was held February 18th. The program consisted of: "Personal Experiences in South African Gold and Diamond Mines," by Thomas Lane Carter, late manager of the French Rand Gold Mine, Johannesburg.

On February 13th, the Section gave a breakfast at La Renaissance des Chenes Verts in honor of the visiting chemists and attorneys in the Bleached Flour Case and other prominent persons.

The thirty-ninth meeting was held at the Directors' Room of the Board of Trade, New Orleans, La., Friday, March 18th, at 8 P.M.

The following papers were presented: "Chemical Examination of

Imported Merchandise," by W. L. Howell. "Some Notes on the Assay of Tincture of Nux Vomica," by G. B. Taylor. GEO. B. TAYLOR, *Secretary*.

KANSAS CITY SECTION.

The February meeting of the Section was held at the new Y. M. C. A. Building, Kansas City, Mo., on Saturday evening, February 19th, at 5 o'clock.

The program began at four o'clock by a visit to the U. S. Assay Office and Laboratories.

At the Y. M. C. A. Building a talk was given by Dr. Charles S. Curtis, U. S. Assayer, Customs Service.

After dinner Dr. Walter M. Cross told the Section about making fertilizer from city garbage.

The March meeting was held at the Chemistry Building, University of Kansas, on Saturday evening, March 12th, at 4 o'clock.

Prof. F. B. Dains, of Washburn College, lectured on "The History of the Development of the Elements."

After dinner Mr. M. Brayton Graff, chemist for the Procter and Gamble Co., spoke on "The Chemical Control of a Soap and Glycerine Factory."

E. A. WHITE, *Secretary*.

CORNELL SECTION.

The February meeting was held Monday, February 21st, in Morse Hall, at 8 P.M.

One hundred members and guests listened to the address, "Problems of the Gas Engineer," by Prof. C. F. Hirshfield.

The March meeting was held in Morse Hall at 8 P.M., Thursday, March 17th, with Dr. J. E. Teeple as speaker on "The Chemical Resources of the United States."

Light refreshments were served as usual. H. W. GILLETT, *Secretary*.

RHODE ISLAND SECTION.

The regular meeting of the Section was held at the University Club, Thursday evening, February 24th.

Dinner was served at 7 o'clock.

Mr. C. E. Swett, of Providence, R. I., then presented the paper for the evening on the subject "Field Notes from the Natural History of Silica."

A special public meeting of the Section, open to ladies and gentlemen, was held in the lecture room of Rhode Island Hall, Brown University, on the evening of Wednesday, March 2nd, at 8 o'clock.

Professor Charles E. Munroe, of Washington, D. C., delivered a stereopticon lecture on "The Testing of Explosives for Use in Coal Mines with Special Reference to the Prevention of Mine Disasters."

ALBERT W. CLAFLIN, *Secretary*.

CHICAGO SECTION.

The February meeting was held at the Kimball Café, on Friday evening, February 25th, at 8.15 o'clock.

The program for the evening was: "Problems of the Linseed Oil Industry," by Otto Eisenschiml, American Linseed Co.

Members of the Section held the usual informal dinner before the meeting.

The Section voted to accept the medal offered by Mr. Converse, and referred the rules for the award of the medal back to the executive committee for further consideration and revision.

A. L. NEHLS, *Secretary*.

NORTHEASTERN SECTION.

The ninety-seventh regular meeting of the Section was held at the Massachusetts Institute of Technology, March 4th.

The following addresses were made: Dr. Daniel F. Comstock, of the Massachusetts Institute of Technology, "Present Conception as to the Constitution of Matter." Mr. M. C. Whitaker, of the Welsbach Co., Gloucester, N. J., "Production of Incandescent Mantles and Chemicals."

KENNETH L. MARK, *Secretary*.

WASHINGTON SECTION.

The one hundred and ninety seventh meeting was held Thursday, March 10th, at 8 P.M., in the Public Library Lecture Hall.

The following program was presented: "The Construction and Equipment of a Chemical Laboratory," by W. D. Bigelow; illustrated with lantern slides; discussion by Chiefs of recently constructed laboratories; presentation of notes, exhibition of apparatus, etc.

J. A. LECLERC, *Secretary*.

SYRACUSE SECTION.

The fifty-seventh meeting was held with the Technology Club at their rooms in the Bastable Block, Friday evening, March 11th.

Dr. A. V. Bleininger, gave an illustrated address on "The Manufacture and Testing of Refractory Material."

WM. H. MCLAUCHLAN, *Secretary*.

SECTION OF EASTERN NEW YORK.

The March meeting of the Section was held in the Electrical Engineering Department of The Russell Sage Laboratory, Rensselaer Polytechnic Institute, Troy, on Friday evening, March 11th, at 8.15 o'clock.

The paper of the evening was: "Wireless Telegraphy and Telephony," by Mr. Wynant J. Williams. The lecture was experimentally illustrated.

R. C. ROBINSON, *Secretary*.

NEW YORK SECTION.

The sixth regular meeting of the session of 1909–'10 was held at the Chemists' Club on March 11th.

The following officers were elected for the session of 1910–'11: *Chairman,* Chas. Baskerville; *Vice-Chairman,* Samuel A. Tucker; *Secretary and Treasurer,* C. M. Joyce; *Executive Committee,* Morris Loeb, G. W. Thompson, J. E. Crane and Arthur E. Hill.

The following papers were read: "The Determination of Copper in Blister and Refined Copper," by Wm. C. Ferguson. "Scrubbing Device for Vacuum System in the Laboratory," by Chas. Baskerville. "Rack for Holding Reagents in Bulk," by J. L. Sporer. "An Improved Ethylene Generator," by V. L. King. "A Constant Temperature Drying Oven and Gas Regulator," by H. T. Beans. "An Automatic Pipette," by S. H. Beard. Description of a Modified Pettersson and Palmquist Apparatus," by C. T. Graham Rogers. "Tests of Iron Wire for Standardization Purposes," by C. H. Stone and C. E. Cheeseman.

C. M. JOYCE, *Secretary.*

CALIFORNIA SECTION.

The fiftieth regular meeting of the Section was held on Saturday evening, March 12th, at 8 o'clock.

An address on "The Electrical Precipitation of Suspended Matter," was given by Dr. F. G. Cottrell, of the University of California.

The usual informal dinner preceded the meeting.

CHARLES ASH, *Secretary.*

CINCINNATI SECTION.

The one hundred and fifty-eighth regular meeting took place Tuesday evening, March 15th, at 8 o'clock, at the Lloyd Library.

Prof. John Uri Lloyd gave the Section a stereopticon evening concerning the Indians of the West, entitled "A Journey through the Navajo and Moqui Indian Countries," with stereopticon views of the Cliff Dwellers' Region.

ALFRED SMITH, *Secretary.*

PHILADELPHIA SECTION

The regular meeting of the Section was held at the Engineers' Club, Philadelphia, Thursday evening, March 17th, at 8 o'clock.

A paper on "The Evidence Obtained during the Past Twelve Years for the Solvate Theory of Solution" was given by Harry C. Jones, Prof. of Physical Chemistry at Johns Hopkins University.

The usual informal dinner was served at the French Club at 6.30 P.M.

F. E. DODGE, *Secretary.*

MINNESOTA SECTION.

The March meeting of the Section was held on Friday evening, March 18th, at 8 P.M. in the Chemical Laboratory of the University of Minnesota. Professor Louis Kahlenberg, of the University of Wisconsin, addressed the Section on "The Chemical Replacement of the Metals by Each Other."

FRANCIS C. FRARY, *Secretary.*

DECEASED MEMBERS.

Reuben Tharp, Jr., San Lorenzo, Calif.

Harold Rollins Wade, Bureau of Chemistry, Washington, D. C.

Oliver Wolcott Gibbs.

When Oliver Wolcott Gibbs died, on December 9th, 1908, American chemists were bereft of one of their leaders, to whom they could look, with affectionate respect, as a pioneer in research, and the true example of the tireless seeker after truth, withal an earnest patriot and a noble gentleman. He was never at the head of a great university laboratory, and the last twenty-five years of his life were spent in retirement from all academic duties; no great body of students are left to mourn the loss of their former teacher. He wrote comparatively few papers of general interest and no books; he shrank instinctively from appearing in the public eye, and the idea of making even an informal after-dinner speech was hateful to him. His austere demeanor and dignified reserve must have always prevented his gaining popularity with the masses, even if his tastes had not led him to prefer scholarly seclusion. To what, then, shall we ascribe the influence which he wielded in the world of chemistry, so that foreign as well as American institutions of learning delighted in showering honors upon him, and considered themselves fortunate if they could obtain his coöperation and advice? Was it not because we all realized that this was a true High-Priest of knowledge, a guardian of the sanctuary, rather than an exploiter of its mysteries; one who could read without an accusing pang, that beautiful distich in which Schiller says of Science:

> Einem ist sie die hohe, die himmlische Goettin, dem Andern
> Eine tuechtige Kuh, die ihn mit Butter versorgt.

Gibbs, a man of modest wants, was probably always possessed of such means that he could restrict himself to the academic side of his profession, and his family traditions and early training would hardly have fitted him for business. I remember conversations with him about the successful careers of his friends, A. W. Hoffman and Joseph Wharton, which made it clear that he would not have attacked a technical problem with any degree of confidence. Perhaps, therefore, a knowledge of his own limitations may have assisted his natural predilections in determining the direction of his work toward pure, one may almost say abstruse, science. But his contemporaries saw a man seeking truth for truth's sake, and they put their trust in this disinterestedness, as well as in his scientific acumen and experimental skill. Justly conscious of his own worth, he was quick to recognize what was meritorious in the work of others, and to applaud, without reserve, the advances along lines quite foreign to his own point of view, while maintaining an almost pathetic veneration for his own great masters, between whom and the present generation he remained one of the last links. Cant, religious, moral or scientific, was abhorent to him, and he could be cruelly caustic in his denunciation of what he deemed charlatancy or insincerity. On the other hand, where he once placed his trust, he left it implicitly, and, when his advice and help were sought, in good faith, he gave of his best. In appearance, and in some respect manners, he resembled James Russell Lowell, to whom I believe he was distantly related. It would have taken considerable boldness to be flippant in his presence, and his students, at all periods of his life, seem to have stood in great awe of him. But he was dearly beloved by friends in and out of academic circles, and he seemed to have the power of impressing his own enthusiasm upon those with whom he collaborated for the public good, as well as for the advancement of science. The Union League and Century Clubs, of New York City, owe their foundation largely to his efforts, just as did the National Academy of Science in Washington; his effectiveness as a member of the U. S. Sanitary Commission, during the Civil War, seemed to have exacted the life-long respect of all his associates.

While, therefore, it was an inestimable gain to the Lawrence Scientific School to secure this master of research, one cannot help wondering whether the narrowness which kept him out of his own alma mater, and forced him to leave the city of his birth, did not curtail some of his most useful powers. Furthermore, the policy which subsequent events have proven thoroughly mistaken, of reducing the Lawrence Scientific School in 1871 from its status as virtually a graduate faculty of natural and exact science, to a shadowy existence as an appendage of Harvard College, deprived Prof. Gibbs of his teaching laboratory, and barred American students of chemistry from working under the direction of a guide who remained for another quarter of a century the master of inorganic research. In fact, during less than eight years of his entire career was he in a position to assign topics for independent research to students in his laboratory, and thus carry out those parallel tests which are the great resource of the modern university professor. Thus it is that the figure of Wolcott Gibbs, even though so recently faded from our eyes, towers in our memory like that of one of the early frontiersmen blazing out new paths in a primeval forest; like the heroes of James Fennimore Cooper, who seek the wilderness from love of nature, not from hatred of man, and who are solitary, not from a saturnine disposition, but from lack of followers willing to forsake easy harvests for the chances of a laborious chase.

But to those who were his immediate contemporaries, Gibbs could not have appeared as a recluse. In the *American Journal of Science*, he was for twenty-two years the eloquent interpreter of the trend of chemistry to workers in other fields of science, and, similarly, the early volumes of the *Berichte der deutschen chemischen Gesellschaft* contain his concise but adequate reports of the achievements of American chemistry. His understanding and sympathy for other branches of exact sciences was great, and, in fact, thermodynamics and optics received much of his attention: he it was, who first appreciated the work of his namesake, J. Willard Gibbs, and insisted on the reward of the Rumford Medal for that treatise on "Equilibrium in Heterogeneous Systems," which became famous twenty years later, when Le Chatelier rediscovered it for the benefit of modern chemists. I could instance, from personal observation, other judgments rendered by him on scientific matter of less moment, in which the clearness of his vision and the thoroughness of his examination proved that no accidental circumstances led him thus to anticipate the trend of physical thought. His contemporaries were stimulated both by the ideas which he freely placed at their disposal, and by the appreciative discrimination which he exercised toward their own scientific efforts.

Born in New York City, on February 21, 1821, as the second son of Col. George and of Laura Gibbs, he was named after his maternal grandfather, Oliver Wolcott, Secretary of the Treasury under Washington and Adams. His boyhood was chiefly spent on his father's farm at Newtown (near what is now Astoria), L. I., and he was educated at the Columbia Grammar School and Columbia College, from which he received the degrees of A.B. in 1841 and A.M. in 1844. He also graduated in medicine from the College of Physicians and Surgeons in 1845, though he never practiced as a physician. His taste for physics and chemistry developed early; he published one or two papers as an undergraduate, worked with Dr. Robert Hare in Philadelphia in 1842, and went abroad in 1845 to specialize in chemistry, under Rammelsberg and Heinrich Rose in Berlin, and under Laurent, Dumas and Regnault in Paris. Returning in 1848, he lectured at Delaware College and the College of Physicians and Surgeons, and was appointed Professor of Physics and Chemistry at the Free Academy of New York City, now the City College, but then practically of high school grade. Here he taught, chiefly by lectures and recitations, until 1863, when he was called to Harvard to fill the Rumford Professorship on the Application of Science to the Useful Arts, recently vacated by Eben Horsford. Attached to this professorship was the Chemical Laboratory of the Lawrence Scientific School, but this was consolidated with the College Laboratory in 1871, under Professor J. P. Cooke, and Professor Gibbs thereafter limited himself to courses in Physical Chemistry, continuing his chemical investigations with the aid of paid assistants. In 1887, he was made Professor Emeritus, and retired to Newport, R. I., where he had always spent his summers on property long in the possession of his family. Here he built a small laboratory, overlooking the beach, in which he continued to work for another decade, until his waning strength warned him to desist. He had lost his dearly loved wife, Josephine Mauran, shortly before his retirement from Cambridge, and he lived very quietly at Newport, attended by a devoted niece, interesting himself chiefly in horticulture as a pastime. He had little taste for the fine arts, but was passionately fond of nature and a friend of all living things. I vividly remember his indignation, one day, when, in the course of a walk, we came across a contractor who was preparing to lop off from a beautiful old tree a great branch that extended into a street through which he wished to move the villa of a summer resident. When the man refused to listen to remonstrances, I was left to guard the tree, while the Doctor set off to find a policeman and finally routed out the Mayor of Newport, with the result that the house had a quarter mile more to travel and the tree was saved.

I have already stated that Gibbs' opportunity to teach advanced chemistry to students was limited to eight years: Prof. F. W. Clarke has given an authoritative account of his teaching at this period, in his beautiful lecture before the Chemical Society of London, (*J. Chem. Soc.*, 95, 1299). My own experience came later, when I fortunately joined the very small class which attended the course in Chemical Physics to which he confined himself after 1871. The formal part of the lesson was frequently dismissed in a few minutes, in which he handed out his full lecture notes, to be copied at home: the remainder of the hour was devoted to experimentation or to purely informal discussion of problems arising out of the general topic. I do not think that the subject was ever treated exhaustively, but we all felt enriched and stimulated when the hour was over. Unfortunately, the course was not correlated to any other work in the University, and I doubt whether, at any one time, more than a dozen undergraduates knew Professor Gibbs by sight.

Privileged, half a dozen years later, to assist him at his private research laboratory, in Newport, I was able to observe more closely his methods of thought and work. He belonged emphatically to what might be termed the Berzelius type of chemist, basing his views upon an intimate knowledge of the reactions of a selected number of elements, and preferring direct deduction from qualitative or quantitative evidence to the experimental substantiation of a hypothesis reached by inductive speculation. His synthetic researches were chiefly carried out in test tubes, without overexact measurements of reacting quantities, of temperature or other conditions. The elaborate search for an *optimum* production of a given compound, so familiar in recent inorganic work, did not appeal to him and he frequently emphasized his desire to point out the directions in which complex compounds should be sought, leaving their careful study to others. Working with the simplest apparatus, almost exclusively in aqueous solutions, he certainly produced an astonishing number of new compounds, whose correlations be was able to point out with considerable verisimilitude. Perhaps he missed a reaction here and there; but few of his critics have been able to state that they failed to find what he did, when they followed his directions closely. As an analyst, he enriched us with some elegant methods, which are not sufficiently emphasized in text books: the determination of manganese as pyrophosphate; the use of mercuric oxide instead of a fixed alkali in precipitating various acids with mercuric nitrate improvements in the estimation of bases as sulphates and oxalates; the detection of cerium by means of bismuth tetroxide or lead peroxide; the use of luteocobalt salts to characterize various acids. The determination of metals by electrolysis, the operation of difficult fusions downward instead of upward, the use of a comparison tube in eudiometric measurements, were all methods first published by him, and many methods developed by others were due to his suggestions. In physics, he early remedied defects in some types of galvanic cell, now obsolete, and he devised improvements of considerable value in the prism spectroscope.

A curious departure from his customary work was his reversion, late in life, to physiological chemistry, when he undertook in 1889 with H. A. Hare and later with E. T. Reichert the systematic study of the action of definitely related organic compounds upon animals. His ideal was the establishment of principles whereby the physiological effect of drugs might be enhanced or modified step by step, so as to produce gradations of physiological effect comparable to the shading of the spectral colors. The experimental work was done by his associates and did not progress far enough to lead to definite conclusions upon this idea.

The name of Gibbs will, however, be chiefly associated with his three great researches on the cobaltammines, the platinum metals and the complex acids. The oxidation of cobalt in ammoniacal solutions had been observed by Gmelin as early as 1822; but F. A. Genth first produced well-defined salts of an ammonia-cobalt base in 1847, publishing his results in 1851, in which latter year papers were published in France by Claudet and by Fremy, who defined four distinct series. Gibbs discovered xanthocobalt in 1852, and thereupon associated himself with Professor Genth, then at the University of Pennsylvania, in a thoroughly systematic study, to which Gibbs seems to have contributed the greater portion of the experimental detail. The results were published by the Smithsonian Institution in December, 1856; but the second series of the work was presented by Gibbs alone to the American Academy of Arts and Sciences in 1874 and 1875. These papers are noteworthy for the thoroughness with which each of the many series was studied, analytically as well as synthetically; he not only showed that the same type of cobaltammine could persist through various combinations with different acids, but also proved that certain acid groups, like NO_2, must be frequently considered an integral part of the base, and that this was notably true of the water, considered by others mere crystal-water, which distinguished the composition of the roseo- from the purpureo-cobalts. His researches were the natural foundation of Werner's theory which has gained general recognition during the past fifteen years.

Analogy to cobaltammines appeared to exist in a compound obtained by Fremy in 1844, by the action of ammonium chloride upon potassium osmiate, and Gibbs proved this, in a brief note published with Genth in 1857, by showing that chlorine could be replaced by other negative radicals without altering the Os: NH_3 ratio. In his final paper, in 1881, he named these compounds the Osmyl-tetramine series. But he was deflected from the continued study of the amines of the platinum group, which he had evidently proposed to himself in 1858, by the interest which the separation and complete characterization of these metals themselves had excited. Working chiefly with refractory California ores, he found it necessary to develop new methods of attack, and his work may well be placed by the side of Claus, Willm and St. Clair-Deville.

Meanwhile, the platin-amines were fully studied by other observers, and Gibbs rather devoted his attention to the behavior of the platinum group to acids. In 1877 he found that the oxides of these metals would unite with the tungstates, to form the salts of complex acids, analogous to the silico-tungstates of Marignac, and this was the starting-point for his great researches on the complex acids, which virtually monopolized the remainder of his experimental activity. Beginning with attempts at systematizing the straggling data on silico-tungstates, phospho-tungstates, etc., recorded by other observers, through the preparation of parallel compounds, he was led to draw one element after another into the complicated molecules that gather around the tungstic or prolyldic nucleus. With a large corps of assistants at his disposal, the work would have assumed gigantic dimensions: but, with a single assistant to carry out the most subtile quantitative separations, his theories must, perforce, await mathematical confirmation, and his cabinet must contain scores of unanalyzed compounds. I believe that he regarded the tungstic acids more or less as the inorganic analogues of hydrocarbons, with certain typical arrangements, into which other groups would enter by direct substitution, largely merging their own identity. Probably, the majority of modern investigators ascribe a more important rôle to these elements of lesser atomic mass; but viewed from the standpoint which I have indicated, the work of Gibbs will show a remarkable consistency, just as his experimental data will, undoubtedly, be confirmed in all essentials by the work of his successors.

And thus the American Chemical Society may well inscribe among its immortals the name of an honorary member, with the words of one of his favorite authors:

> Wer es den Besten seiner Zeit hat gleich gethan
> Der hat gelebt fur alle Zeiten.

MORRIS LOEB.

EIGHTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.

On the evening of February 3, 1910, an informal gathering took place at which there were present among others, most of those to whom had been delegated the task of providing for the creation of an organization for the Eighth International Congress of Applied Chemistry, by the London Congress last June; a representative of the Association of Manufacturing Chemists, the American Chemical Society, the American Electrochemical Society, the Society of Chemical Industry were each also present at this informal meeting.

The consensus of opinion was that the greatest success could be expected only if the most effective system and mode of organization could be had, and if each and every chemist in the United States could be made to feel that he himself, directly or indirectly through his professional, business or educational affiliations, had a personal share of responsibility in the conduct and management of the Congress from its very start and to its very end. This was regarded as the proper and correct guide in proposing any plans or schemes of organization.

The Eighth Congress is to convene in 1912 with Professor Edward W. Morley as Honorary President and Dr. W. H. Nichols as Acting President at a time and place to be determined by the Organization of this Congress. The most important part of the Congress, in fact that by which its value and real success will be measured, is the amount of original matter both scientific and technical, which it will be able to present to its members. To this end, every chemist in America who has or may have any original matter to present to this Congress should begin without delay to prepare such matter, and have it in shape so that it may be presented to the Congress in ample time for proper printing, classification and distribution to members and the technical and scientific press.

The Congress, being held in the United States, will, with a great deal of right, naturally look to a very good showing from the chemists of the United States, and every chemist in this country, which is to be host to our foreign colleagues, should constitute himself a committee of one to get from himself, or from his friends as much scientifically or technically valuable material as possible so that the proceedings and publications of the Eighth Congress may correctly reflect the true mental attitude of the chemists of the United States towards their profession, both as a pure science and as a part of the industrial activities of this country.

It is the hope that the Program Committee will be able to begin its activities effectively before the close of 1910, but in the meantime it behooves every chemist in the United States actively and energetically to consider how and in what way he can best contribute to the success of this Congress, and particularly in the direction of papers and communications to the Congress embodying the advance in this field since June, 1909, the date of the last Congress.

At a meeting to be held in April or May, 1910, by those charged with the duty of providing suitable organization for the Eighth Congress, some definite action as to such organization may be looked for. Those who have that responsibility are making every effort to get as many suggestions as to divisions of organization, mode of organizing and membership of the organization as possible. Every one interested in having this organization on as broad foundation as possible is earnestly invited to present any suggestions that may be helpful in that direction, in writing by the middle of April, 1910, so that all these suggestions may be properly classified and collated and put in condition for most thorough consideration before the meeting above referred to actually takes place. Such communications may be addressed to the temporary secretary, Dr. B. C. Hesse, 90 William Street, New York City.

NEW EDITION OF GMELIN-KRAUT'S HANDBOOK.

Professor Dr. Franz Peters, Gross-Lichterfelde I, Verl. Wilhelmstrasse 26, writes to the Bureau of Standards that he has assumed the editorship of Gmelin-Kraut's "Handbook of Chemistry," 7th edition, since the death of Professor Friedheim, and is arranging for an 8th edition. In order to add to the value of these publications he desires to cover the American field fully and would therefore like to have access to original publications in chemistry and physics. He expresses the wish also to receive copies of all dissertations, relating to inorganic chemistry, of the universities of the United States. This request is made public for the information of authors of dissertations as well as the heads of faculties of chemistry.

Proceedings.

COUNCIL.

By letter ballot sent to the Council on March 4th, the Council voted unanimously that the Secretary be directed to send to the treasurer of the committee in charge of the erection of a monument to Marcelin Berthelot the funds collected by the circulation of a subscription paper at the recent General Meeting of the Society. The amount collected from individuals, amounting to $131.50, has been duly forwarded

In the same communication to the Council the following statement and motion was put and the motion was carried with only two dissenting votes.

"Last fall the Secretary wrote to the head of the chemical department in each of our prominent educational institutions asking him for a list of his alumni engaged in chemical work. This list was then checked off and he was asked to send a letter to each non-member of the Society, the clerical work and postage being furnished by the Secretary's office. As a result some three hundred new members were secured. An interesting fact developed during this correspondence, *viz.*: that our membership among the chemical alumni of the various institutions varied with the particular institution between ten and ninety per cent. It was also noted that those having the larger percentage were those who now urge their senior students to join us. From this fact and many others, the Secretary was impressed with the idea that the future of our Society, and to a lesser extent its present, depends on early interesting those who are to take our places later, for very few students who interest themselves in the profession at large and gain the habit of having our publications on their desks during their under-graduate life leave us later.

"This matter was presented in the form of a motion to the Council at Boston and was referred by them to a committee consisting of A. A. Noyes, T. W. Richards and H. P. Talbot to carefully consider its advisability and legality under our Constitution and By-laws and the requirements of the Post Office Department as to subscribers. This committee have carefully considered the matter and report unanimously the following motion:

"'Under-graduate students may become members of the Society without payment of membership dues during their college course, including the year of their graduation, by making appropriate application and by subscribing to one or more of the Society's publications.'"

MEMBERS ELECTED BETWEEN MARCH 15TH AND APRIL 15TH.

Appell, Geo. M., Hotel Denechaud, New Orleans, La.
Atwood, Edward M., Box 484, Seymour, Conn.
Bandt, Helmuth F., 224 Brooks St., Madison, Wis.
Berry, Jessie V., 1155 Jackson St., Oakland, Calif.
Bose, Amulya C., University of Pittsburgh, Pittsburgh, Penna.
Bosworth, Alfred W., N. Y. Agric. Exper. Station, Geneva, N. Y.

Boyer, G. Hewitt, c/o Continental Portland Cement Co., Jefferson Barracks, Mo.
Bracewell, Geoffrey A., 20 Heaton Grove, Bradford, England.
Brown, Irving C., 533 Sims Hall, Syracuse Univ., Syracuse, N. Y.
Canis, E. N., 2221 Park Ave., Indianapolis, Ind.
Chandler, Louis C., 19th Floor, 1st Nat'l Bank Bldg., Cincinnati, Ohio.
Chapin, Joseph E., 458 Prospect Place, Brooklyn, N. Y.
Clapp, Albert L., 552 Washington St., Braintree, Mass.
de Meeus, E., c/o Michelin Tire Co., Milltown, N. J.
Derby, John H., Jr., 12 Bellaire Drive, Montclair, N. J.
Dobroserdov, Dmitri K., Pokrowskajastreet 14, Kasan, Russia.
Dole, Norman E., 749 Hayes St., San Francisco, Calif.
Evans, Albert W., 5468 Ellis Ave., Chicago, Ill.
Fabinyi, Rudolf, Chemical Inst. of the University of Kolozsvar, Hungary.
Fitch, William W., c/o A. R. Arguelles, Baracoa, Cuba.
Frevert, Gustav E., Moscow, Idaho.
Fulton, Horace M., 1720 Willard St., N. W., Washington, D. C.
Gibbs, Arthur E., Wyandotte, Mich.
Gravelle, Philip O., 183 W. 87th St., New York City.
Hunt, George M., 2323 College Ave., Berkeley, Calif.
Illes, Arpad E., 4494 Forest Park Boulevard, St. Louis, Mo.
Jenckes, Edwin K., 225 Newbury St., Boston, Mass.
Kammerer, Alfred L., Tower Grove and Flad Aves., St. Louis, Mo.
Keeble, Horace, Wereham Hall, Stoke-Ferry, Norfolk, England.
Kendall Mfg. Co., Providence, R. I.
Kitchen, William J., 10-12 Queen St., Melbourne, Australia.
Knowlton, Helen, 27 Central St., Beverly, Mass.
Kressel, Edward C. L., 827 Washington St., Hoboken, N. J.
Leasman, E. L., 901 University Ave., Madison, Wis.
Lehn and Fink, 120 William St., New York City.
MacGregor, H. P., 1907 Division St., Nashville, Tenn.
Marsh, Harry, 430 East A St., Moscow, Idaho.
McDanell, Louise, 100 S. 4th St., Alhambra, Calif.
McElroy, K. P., 197 Pearl St., New York City.
McKesson, Donald, 91 Fulton St., New York City.
Merrell, Lewis C., 502 W. Onondaga St., Syracuse, N. Y.
Mitke, Charles A., 726 Yale Station, New Haven, Conn.
Mukerji, Prafulla C., University of Pittsburgh, Pittsburgh, Penna.
Nicholas, H. E., Eastport, Maine.
Pedersen, Arthur Z., Beach Lane, So. Bensonhurst, Brooklyn, N. Y.
Perkins, H. Z. E., 128 N. Peters St., New Orleans, La.
Platts, Howard C., 38 Sylvan St., Rutherford, N. J.
Putt, Earl B., 711 Tenth Ave., North, Fargo, N. D.
Sarles, Edgar H., 2713 Norwood Ave., Norwood, Ohio.
Saunders, Charles W., 740 Hope St., Shreveport, La.
Scales, Robert R., Greenville, So. Car.
Schmidt, George C., Bureau of Chemistry, Washington, D. C.
Sheridan, A. L., 9240 Manistee Ave., Chicago, Ill.
Shimomura, Kotaro, Shinkanasumaru Kojinguchi Sagaru, Kyoto, Japan.
Sieplein, Otto J., Grove City, Penna.

Smart, Robert, 113 Whiting Bldg., Albuquerque, N. M.
Sprau, R. L., 1108 Logan St., Louisville, Ky.
Steese, Marcus, c/o Ohio Iron-Steel Co., Lowellville, Ohio.
Tarbell, R. F., c/o United Zinc & Chem. Co., Kansas City, Kans.
Tays, James A., c/o City National Bank, El Paso, Texas.
Treadwell, John C., Viesca, Coah., Mexico.
Turley, Everett W., 1038 E. 46th St., Chicago, Ill.
Ullmann, Albert T., Box 30, Chillagoe, Queensland, Australia.
Walker, Seth S., 418 East 2nd St., Mishawaka, Ind.
Walster, Harlow L., College of Agriculture, Madison, Wis.
Weinstock, Sidney, 2224 North Lambert St., Philadelphia, Penna.
Wey, W. G., 6151 Kimbark Ave., Chicago, Ill.
Whitehouse, Joseph, 603 Washington St., Versailles, McKeesport, Penna.
Williams, John M., 218 Water St., Perth Amboy, N. J.

MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons, Durham, N H.]

INDIANA SECTION.

The following papers were presented at the regular meeting of the Section, held Friday, March 11th, at 7.30 o'clock, in the office of the State Food and Drug Laboratory

"Glass Sands and Ball Clays of Florida," H H. Buckman. "On the Purpose and Methods of the Chemistry Course in the Public High School," F. B. Wade. "The Teaching of Chemistry in the University," J. H. Ransom.

Supper was served at 6 15 o'clock.

A D. THORBURN, *Secretary*

ST. LOUIS SECTION.

The March meeting of the Section was held, in conjunction with the St. Louis Chemical Society, on the evening of March 14th, at the St. Louis Academy of Science Building. The speaker of the evening was Mr. R. F. Weber, who was one of the body of American teachers appointed last year to visit the schools of Germany. Mr. Weber's subjects were: "Chemistry in America and Germany" and "Electrolytic Preparation of Hydrazine." Dr. H. W. Wiley was present and entertained the members by recounting some of his experiences while a student in Germany.

The April meeting was held at the Academy of Science Building, Monday evening, April 11th. The following papers were presented: "Terpineless Extract of Lemon and Analysis Thereof," by Dr. S. H. Baer. "A Rapid Method of Estimating Iron in Iron Ores," by Dr. LeRoy McMaster. "Ozone in Water Treatment" (illustrated with lantern slides, and apparatus for domestic treatment of water with ozone), by Mr. W. F. Monfort.

As is usual the meeting was held in conjunction with the St. Louis Chemical Society.

R. NORRIS SHREVE, *Secretary.*

CHICAGO SECTION.

The March meeting was held at the Kimball Café, on Friday, March 18th, at 8.15 o'clock. The address for the evening was: "The Chemist in a Brass Foundry," by W. M. Corse, Secretary of the American Brass Founders' Association.

After the paper of the evening the Section again took up for discussion the rules for the award of the medal offered by Mr. Converse.

The usual dinner was held before the meeting.

The April meeting, preceded by the usual dinner, was held at the Kimball Café, on Friday evening, April 15th, at 8.15 o'clock, with 120 in attendance. The topic of the evening was: "The Borax Industry, the Mining and Manufacture of Borax and Its Uses," with papers as follows: "The Development of the Borax Industry in California and Nevada, and Sources of Supply in Other Countries," S. T. Mather, Thorkildsen-Mather Co. "Mining and Refining of Borax," F. M. Dupont, Chemist for the Sterling Borax Co. "The Use of Borax in Manufacturing Enameled Sanitary Ware," C. J. Wolff, L. Wolff Manufacturing Co. "The Use of Borax in Manufacturing Enameled Kitchen Ware," Howard Coonley, Coonley Manufacturing Co. The papers were profusely illustrated with specimens of borax ores, borax, and the manufactured products therefrom.

A. L. NEHLS, *Secretary.*

NEBRASKA SECTION.

The fifty-ninth annual meeting of the Section was held in the lecture room of the Chemical Laboratory of the University of Nebraska, Saturday, March 19th, at 8 P.M. The following program was presented: "Present Status of the Bleached Flour Controversy," Dr. F. J. Alway. "Analysis of Soaps," S. H. Ross. "Nitrogen Problems and Dry Farming," R. S. Trumbull. "Determination of Humus," E. K. Files.

O. L. BARNEBEY, *Secretary.*

LOUISVILLE SECTION.

The regular March meeting of the Section was held in Louisville on the 19th. The Louisville members entertained the Lexington, Georgetown and Winchester members at a dinner at noon at the Galt House. The following papers were given: "Antitoxins," Dr. L. A. Brown, of the Food and Drugs Laboratory, Lexington, Ky. "Liquid Mixtures of Constant Boiling Point," Dr. Garnett Ryland, Georgetown, Ky. "Possible Variation in the Composition of Distillers' Dried Grains," Dr. A. M. Peter, Lexington, Ky. "Operation of the Louisville Filter Plant," Mr. W. H. Lovejoy, Chief Chemist of the plant.

Following the papers a trip was made to the Filter Plant where the details of operation were explained.

The April meeting was held at 8 P.M. on the 11th, in Room 700 of the Atherton Building.

Dr. A. M. Peter, Chief Chemist at the Kentucky Agricultural Experiment Station, gave an account of the occurrence of zinc in a large number of Kentucky mineral waters which had been examined at the Station.

Mr. F. M. Scales, of the Louisville Filter Plant, spoke on the "Bacteriological Examination of Water."

The usual light refreshments were served. F F HASBROUCK, *Secretary*

MILWAUKEE SECTION.

The regular meeting of the Section was held at the Trustees' Room, Milwaukee Public Museum, Friday evening, March 25th, at 8 P.M. A paper on "The Methods of Production and Properties of the Chemical Dry Colors" was presented by Mr. C. H. Hall, Supt. of Dry Color Dept., Patton Paint Co. H. M SOPER, *Retiring Secretary.*

RHODE ISLAND SECTION.

The regular meeting of the Section was held at the University Club, Thursday evening, March 31st.

After dinner Professor William H. Kenerson, of the Engineering Department of Brown University, presented the paper of the evening on "Some Problems of the Testing Laboratory." ALBERT W CLAFLIN *Secretary*

NEW YORK SECTION.

The seventh regular meeting of the Section of 1909-'10 was held at the Chemists' Club, on Friday, April 8th.

Dr. F. D. Dodge read a paper entitled "Notes on the Determination of Essential Oils." The remainder of the program consisted of a Symposium on Leather, arranged by Dr. Allen Rogers, which included the following papers: Allen Rogers, "General Outline of the Leather Industry." Alan A. Claflin, "The Process of Bating." John H. Yocum, "Vegetable Tanning Materials." Otto P. Amend, "Recent Advances in Chrome Tannage." F. E. Atteaux, "The Coloring of Leather" (read by Dr. Rogers). Edgar A. Prosser, "Oils Used in the Leather Industry."

C M. JOYCE, *Secretary.*

SECTION OF EASTERN NEW YORK.

The April meeting was held in the Schenectady High School Auditorium, Wednesday evening, April 13th, at 8 o'clock. The paper of the evening was on "Usefulness of Chemistry in Sanitation," by Dr. H. W Wiley, Chief of Bureau of Chemistry, Department of Agriculture, Washington, D. C. At 6 o'clock a subscription dinner in honor of Dr. Wiley was held by the members at the New Vendome Hotel. R. C. ROBINSON, *Secretary.*

CINCINNATI SECTION.

The 159th regular meeting of this Section was held on Wednesday evening, April 13th, at the Lloyd Library. The speaker for the evening was Dr. Alfred Springer, who discussed the following subjects: (*a*) "Salt." (*b*) "Yellow Fever."

ALFRED SMITH, *Recording Secretary.*

WISCONSIN SECTION.

The April meeting of the Section was held at Madison on Wednesday, April 13th, at 8 P.M., in Room 102 of the Chemistry Building. Dr. H. Stanley Bristol, of the Forest Service, U. S. Department of Agriculture, presented a paper on "Some Chemical Problems of the Forest Products Laboratory."

E V McCOLLUM, *Secretary.*

WASHINGTON SECTION.

The 198th meeting and annual smoker was held Thursday evening, April 14th, at 8 P.M., at Fritz Reuter's.

The Smoker began with a beefsteak dinner at 6.30. The regular meeting was called to order at the same place at 8 o'clock and the following program presented: Reid Hunt, "The Effect of Drugs and Diet upon the Thyroid." B. Herstein and Lyman F. Kebler, "Contribution to the Knowledge of Phosphoric Acids." H. C. Fuller, "Separation and Determination of Cocaine and of Atropine from Strychnine."

J A. LE CLERC, *Secretary.*

LOUISIANA SECTION.

The fortieth meeting was held at the Directors' Room of the Board of Trade, New Orleans, Friday, April 15th, at 8.00 P.M. The paper of the evening was "Food in Light of Modern Chemistry," by Dr. Gustav Mann.

GEO B. TAYLOR, *Secretary*

MINNESOTA SECTION.

The twenty-fifth regular meeting of the Section was held Friday evening, April 15th, in the Ohemical Laboratory of the University of Minnesota, with program as follows: "A Correction in the Beckmann Thermometer Due to the Hydrostatic Pressure of the Mercury Column," Prof. Ira H. Derby. "Comparison of Rapid Electroanalytical Methods: Part 1, The Determination of Copper," Francis C. Frary and Andrew P. Peterson.

FRANCIS C. FRARY, *Secretary*

DECEASED MEMBER.

Henry A. Torrey, Harvard University, Cambridge, Mass., March 26, 1910.

Issued with the June Number, 1910.

Proceedings.

COUNCIL.

MEMBERS ELECTED BETWEEN APRIL 15TH AND MAY 15TH.

Adams, Elliot Q., Res. Lab'y, Gen. Electric Co., Schenectady, N. Y.
American Vanadium Co., Pittsburg, Penna.
Ames, W. B. V., 151 Wabash Ave., Chicago, Ill.
Bailey, Clyde H., Agricultural College, Fargo, N. D.
Blauer, I. Theodore, 317 E. 90th St., New York City
Brown, Chas. Wm., 11 W. Michigan St., Chicago, Ill.
Cheney, Gough L., Mt. Pleasant, Iowa
Cooper, J. D., 2408 Longest Ave., Louisville, Ky.
Davis, Eugene R., 149 Rector St., Perth Amboy, N. J.
Dennis, Arthur C., Deerwood, Minn.
Edeler, A., c/o Proctor & Gamble Co., Kansas City, Kans.
Elley, Harold W., Sta. A, Chem. Bldg., Lincoln, Nebr.
Elmer, James M., Tuolumne, Calif.
Enoch Morgan's Sons Co., 439 West St., New York City.
Fairhall, Lawrence T., Danville, Ill.
Forst, Leo B., 1529 Tea St., Washington, D. C.
Garland, Charles S., 18, Derwent Grove, E. Dulwich, London, S. E., Eng.
Graham, Alexander E., Agric. Bldg., Univ. of Calif., Berkeley, Calif.
Guhlmann, Charles F., Grantwood, N. J.
Hadank, Erich, 523 River St., Hoboken, N. J.
Harms, Herman, 48 S. Main St., Salt Lake City, Utah.
Haskell, William O., Orono, Maine
Herstein, Bernard, 1744 Willard Ave., Washington, D. C.
Hess, J. Royden, 163 No. Main St., Phillipsburg, N. J.
Heuser, August, 1367 Sunnyside Ave., Chicago, Ill.
Hoyt, Leslie J., Hillsboro, Ohio.
Jaquish, Ben M., 782 East 18th St., New York City
Kennedy, Miles Bryce, Univ. of Nevada, Reno, Nevada.
Kennedy, Robert P., 119 Stewart Ave., Ithaca, N. Y.
Kudlich, Herman F., Jr., 153 West 21st St., New York City.
Lamont, Charles, 1111 Union Trust Bldg., Detroit, Mich.
Lipstate, W. A., Hartley Hall, Columbia University, New York City.
Lowe, James O., 516 Englewood Ave., Chicago, Ill.
Loy, Sylvester K., Johns Hopkins University, Baltimore, Md.
MacKey, John F., 1428 Tennessee St., Lawrence, Kans.
Marbaker, Edward E., 1615 N. 55th St., Philadelphia, Penna.
Martin, Herbert W., 5225 Woodlawn Ave., Chicago, Ill.
Mason, Stephen N., Ayer Mills, Lawrence, Mass.
McAllister, H. T., $1002^{1}/_{2}$ California Ave., Urbana, Ill.
Mitchell, Thomas A., 79 Elm St., North Woburn, Mass.
Monro, Claxton, 16 Elm St., North Andover, Mass.
Murray, W. S., Lock Box 873, Hamilton, N. Y.
Patton, Walter D., Memorial University, Mason City, Iowa.
Peterson, Leo, Box 331, Emporium, Penna.

Phillips, Percy P., Rurki, United Provinces, India.
Pollock, Frank S., 237 E. Mauch Chunk St., Tamaqua, Penna.
Pritz, Wesley B., 1852 W. 112th St., Cleveland, Ohio.
Rauchfuss, Arthur A., 526 9th St., Brooklyn, N. Y.
Reid, W. D., 2604 St. Mary's Ave, Omaha, Nebr.
Rice, Edward W., Box 358, Santa Cruz, Calif.
Rogers, Rutherford H., 902 Mahoning Ave., Youngstown, Ohio.
Schoellkopf, Jacob F., Jr., 211 Anderson Place, Buffalo, N. Y.
Shepherd, John H., 1443 E. 66th St., Chicago, Ill.
Southern Cotton Oil Co., 24 Broad St., New York City.
Steffens, J. A., Box 278, Spring Valley, N. Y.
Steinkoenig, L. A., Station and Elliot Aves., Arlington Heights, Ohio.
Trenthardt, Ernest L. P., c/o W. B. Alwood, Charlottesville, Va
Wanner, H. E., Box 137, Annville, Penna.
Winkler, John, 2214 Union St., Berkeley, Calif.

MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons, Durham, N. H.]

UNIVERSITY OF MISSOURI SECTION.

The seventh meeting of the University of Missouri Section was held Friday evening, March 4th, at the home of Professor Hermann Schlundt. A supper was given at 6 o'clock in honor of the speaker, C. W. Green, at which a number of invited guests were present. After the supper Professor Green addressed the Section on the "Changes in Chemical Composition of Salmon during the Spawning Season."

The eighth meeting of the Section was held March 18th at 7.30 P.M. Mr. L. D. Haigh gave a review of Lawes and Gilbert's work on "Chemical Composition of Some of the Animals Slaughtered as Human Food," and also of Professor Paul Schweitzer's work at the Missouri Station on the "Flesh of Beef Animals."

The ninth meeting of the Section was held Friday evening, April 1st. Professor Sidney Calvert addressed the Section on "Some New View Points in Organic Chemistry."

The tenth meeting of the Society was held Saturday morning, April 23rd. Mr. H. S. Miner, Chief Chemist of the Welsbach Light Company, gave a very interesting address on the "Chemistry of the Rare Earths, with Special Application to Incandescent Lighting."

The eleventh meeting of the Section was held Friday afternoon, April 29th. Professor Hermann Schlundt gave an address on the "Alpha Particle."

C. ROBERT MOULTON, *Secretary*.

INDIANA SECTION.

The regular meeting was held Friday, April 8th, at the Hotel English. F. R. Eldred read a paper on "Deterioration of Various Drug Extracts." E. G. Eberhardt, who is a delegate to the Pharmacopoeial Convention, presented a paper on "The Coming Revision of the United States Pharmacopoeia." The following delegates to the Convention took part in the discussion: J. R. Francis, A. D. Thorburn, W. H. Foreman and C. R. Schaeffer. "The Pharmacopoeia as a Legal Standard in Municipal and State Work" was discussed by H. E. Barnard.

A. D. THORBURN, *Secretary.*

UNIVERSITY OF ILLINOIS SECTION.

The thirty-first regular meeting of the Section was held April 19th, at the Chemistry Building.

The topic of the evening was "Gas Calorimetry," presented by Professor S. W. Parr. The discussion was made very interesting with exhibits and demonstration of apparatus.

This was the annual meeting of the Section, and officers for the ensuing year were elected as follows: *Chairman*, E. W. Washburn; *Vice-Chairman*, P. B. Hawk; *Councilor*, E. Bartow; *Secretary*, Grinnell Jones; *Treasurer*, C. W. Balke.

The annual reports of the officers showed a flourishing condition of the Section.

L. H. SMITH, *Secretary*

A meeting of the Section was held on Tuesday, May 17th, at 7.30 P.M., in the Chemistry Building.

Professor R. C. Curtiss spoke on (1) "Condensations in the Mesoxalic Ester Series." (2) "The Acid Products of the Action of the Red Oxides of Nitrogen on Malonic Esters." Mr. D. A. MacInnes presented "A Comparative Study of the Freezing Points, Conductivities and Viscosities of Aqueous Solutions of Electrolytes Belonging to the Same Ionic Type but Differing in Degree of Hydration." An exhibition of the apparatus used in the investigation accompanied this paper.

GRINNELL JONES, *Secretary*

PITTSBURGH SECTION.

The April meeting was held in the Engineering Building of the University of Pittsburgh, Thursday evening, April 21st. The following interesting papers were read: "Aluminum in Industrial Engineering," by Mr. Earl Blough, Chief Chemist of the Aluminum Company of America, "Thermochemistry of Explosives," by Dr. W. O. Snelling, Chief in Explosives Laboratory, U. S. Geological Survey, Pittsburgh, Pa.

The regular meeting was held in the Carnegie Technical Schools, on Thursday evening, May 19th.

Program: "The Explosive Power of Coal Dusts; A Method of Testing," Joseph C. W. Fraser, Chemist on Coal Research, U. S. Geological Survey. "The Materials Laboratory of The Public Works Department of Pittsburgh," by M. S. Evans, Chief Chemist.

JOHN A. SCHAEFFER, *Secretary.*

SYRACUSE SECTION.

The fifty-eighth meeting was held at the University Club on April 22nd, at 8.00 P.M. Mr. Clifford Richardson addressed the Section on the subject of "Road-making Material."

WM H MCLAUCHLAN, *Secretary*

KANSAS CITY SECTION.

The Section met at Washburn College, Topeka, on Saturday, April 23rd, at 2 P.M.

After a visit to the College the members listened to the following addresses: "Chemistry Fifty Years Ago at Yale," Dr. J. T. Lovewell. "Some Studies in the Reduction of Aldehydes and Ketones," Prof. J. B. Whelan. "On the Relative Digestibility of Unbleached and Bleached Flour," Prof. J. T. Willard and Prof. C. A. A. Utt. Recess was followed by Dr. Crumbine's address and "Notes on Chemical Topics," by Prof. F. B. Dains.

E. A. WHITE, *Secretary*.

RHODE ISLAND SECTION.

The regular meeting of the Section was held at the University Club, Thursday evening, April 28th.

Dinner was served promptly at 7 o'clock, after which Professor Frederic P. Gorham, of the Biological Department of Brown University, presented the paper of the evening on "Chlorine Disinfection of Water and Sewage."

ALBERT W. CLAFLIN, *Secretary*

NORTHEASTERN SECTION.

The ninety-eighth regular meeting of the Section was held at the Twentieth Century Club, Boston, on April 29th. Prof. Henry Carmichael presented a paper entitled "Electrolysis of Chlorides Theoretically Considered," in which he described the advantages of a partition of asbestos cloth impregnated with Portland cement as a means of separating the electrode products in the electrolysis of brine. Mr. Jasper Whiting, in a paper upon "The Electrolysis of Brine," described in detail his electrolytic cell, which makes use of the formation of sodium amalgam but is not open to many disadvantages possessed by the "Castner Process."

K. L. MARK, *Secretary*

MILWAUKEE SECTION.

The regular meeting of the Section was held April 29th, in the trustees' room in the Milwaukee Public Museum. The program consisted of an illustrated talk on "Opaque White Pigments Used in the Manufacture of Paint," by Frank S. Low, of the Experimental Department of the Patton Paint Co., followed by a general discussion on coal, led by Mr. C. B. Dickie and Mr. G. N. Prentiss.

FRANK S. LOW, *Secretary*.

IOWA SECTION.

The annual meeting was held in the Chemistry Lecture Room of Grinnell College, on Saturday, April 30th, at 9 A.M.

The program was as follows: "Some Suggestions on the Determination of Calcium," George Heise. "The Effect of Continued Grinding on Water of Crystallization," Nicholas Knight. "Laurolene," W. A. Noyes. (As by W. A. Noyes, C G Derrick, and L. P. Kyriakides.) "The Manufacture of Absolute Ether," Launcelot Andrews. "The Modern Manufacture of Portland Cement from the Mechanical and Chemical Standpoint" (illustrated), G. P. Dieckmann. "A New Method for the Determination of Humus," A. A. Wells. "On the Quality of owa Deep Well-Waters," W. S. Hendrickson. "The Efficiency of Land Plaster in Preventing the Loss of Ammonia in Manure," W. W. Scott. Reports.

The following officers were elected for the year 1910–1911: *President*, C. N. Kinney; *Vice-President*, W. J. Karslake; *Secretary*, J. N. Pearce.

J NEWTON PEARCE, *Secretary*

CORNELL SECTION.

A meeting was held in Morse Hall, May 2nd, at 8 P.M.

The paper of the evening was on "Some New Developments in Limnology," by Prof. J. G. Needham.

H W GILLETT, *Secretary*.

NEW YORK SECTION.

The eighth regular meeting of the Section of 1909–'10 was held on May 6th, at the Chemists' Club. Prof. Julius Stieglitz, of the University of Chicago, gave a talk on the "Electrolytic Theory of Oxidation and Reduction," illustrated by numerous lecture table experiments.

Preceding Prof. Stieglitz' address the following papers were read: Harrison E. Patten, "On the Action of Crushed Quartz upon Nitrate Solutions." A. F. Seeker and W. E Mathewson, "Estimation of Iodine in Organic Compounds and in the Presence of Other Halogens" (read in abstract by F. H. Pough). G. D. Beal and M. T. Bogert, "Stilbazoles in the Quinazoline Group."

C. M. JOYCE, *Secretary*

CALIFORNIA SECTION.

The fifty-first regular meeting of the Section was held on Saturday evening, May 7th, at 8 o'clock, at Tait's Cafe.

The paper on "Electro Metallurgy of Iron on the Pacific Coast," was by Mr. G. H. Clevenger, of Stanford University.

The usual informal dinner preceded the meeting.

CHARLES S. ASH, *Secretary*

ST. LOUIS SECTION.

The May meeting was held in connection with the St. Louis Chemical Society, on the evening of the 9th, at the Academy of Science Building.

"The Tin Plague" was discussed by Mr. Leo. R. A. Suppan; and the results of "A Study of Some Methods Used in Oil Analysis" were given by Mr. J. J. Kessler and Miss G. K. Mathiason. In this latter paper the relation of the physical properties of various oil mixtures to the corresponding properties of the constituents was shown by means of numerous tables and curves.

After the meeting the usual informal social gathering was held.

R. NORRIS SHREVE, *Secretary*.

CINCINNATI SECTION.

The 160th regular meeting of the Section was held on Wednesday, May 11th, at the Lloyd Library, at 8 o'clock.

The speaker for the evening was Mr. P. F. Wehmer, Municipal Chemist for the City of Cincinnati, and the subject for discussion "Creosote Wood Block."

ALFRED SMITH, *Secretary*.

WISCONSIN SECTION.

The May meeting of the Section was held at Madison on Wednesday, May 11th, at 8 P.M., in Room 102 of the Chemistry Building.

Dr. J. Howard Mathews presented a paper on "Processes of Color Photography."

E. V. MCCOLLUM, *Secretary*.

WASHINGTON SECTION.

The 199th meeting was held on Thursday, May 12th, at 8 P.M., in the Public Library Lecture Hall.

The following program was presented: "The Exact Determination of Sulphur and of Barium in the Presence of Alkali Salts," I. K. Phelps. "The Determination of Nitrogen in the Feces," I. K. Phelps. "Oil Cement Concrete," A. S. Cushman. "The Complexity of the Humus Extract of Soils," E. C. Shorey. "The Separation and Determination of Cadmium in Presence of Copper," Edwin A. Hill.

J. A LECLERC, *Secretary*.

San Francisco Meeting.

The following divisions will hold meetings in San Francisco: Industrial Chemists and Chemical Engineers, Physical and Inorganic Chemistry, Organic Chemistry, Agricultural and Food Chemistry. The Rubber Section and the Section of Chemical Education will hold no meeting. The Pharmaceutical and Fertilizer Divisions will be represented and will hold meetings if conditions warrant. Otherwise any papers offered to these divisions will be presented before one of the others. Details as to train, hotel rates, etc., and any additional information received by the secretary before May 25th will be found in the advertising pages of this number.

CHARLES L. PARSONS, *Secretary*.

Proceedings.

COUNCIL.

The following motion of Dr. Morris Loeb has unanimously passed the **Council.**

"Moved, that the Council approve the action of the New York Section **taken at its meeting** on May 6, 1910, looking toward the establishment of **a Museum and** Chemical Loan Collection, and authorize the Section to **undertake** negotiations for the accomplishment of this object, subject, **however, to a review by the Council."** Charles L. Parsons,

Secretary.

Members Elected between May 15th and June 15th.

Barringer, Laurence E., Gen. Electric Co., Schenectady, N. Y.
Bean, M. J., 20 Cross St., Medford, Mass.
Beatty, Cornelius, College Park, Md.
Beringer, George M., Camden, New Jersey.

Ziegler, Walter W., 363 Madison St., Milwaukee, Wis.

MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons, Durham, N. H.]

SECTION OF WESTERN NEW YORK.

The March meeting was held at the University of Buffalo. Mr. G. M. J. MacKay presented a paper on "Cements, Ancient and Modern," describing the recent methods used in making Portland and blast-furnace cinder cement.

The April meeting was held at the Masten Park High School, Buffalo. Prof. E. M. Chamot gave a lecture on "The Microscope in the Chemical Laboratory," illustrated with lantern slides.

The annual election and banquet was held May 20th at Hotel Statler with Vice-President Lidbury in the chair. The following officers for the coming year were elected. *President,* W. H. Watkins; *First Vice-President,* J. I.

Karas; *Second Vice-President*, R. E. Fowler; *Councilor*, F. A. J. Fitzgerald; *Treasurer*, J. Klein; *Secretary*, W. Wallace; *Executive Committee*, F. A. Lidbury, G. H. A. Clowes, A. L. Pouleur.

The presiding officer made an informal address followed by short addresses from each of the elected officers.

The closing hours of the meeting were occupied by listening to remarks of literary interest from many members. Meeting adjourned at 12 P.M.

N. W. SHED, *Retiring Secretary.*

COLUMBUS SECTION.

The regular meeting of the Section was held April 28th in the Chemical Laboratory, Ohio State University. A paper upon "The Recent Developments in the Examination of Proprietary Remedies," dealing vigorously with the ethics of the problems involved, was presented by Prof. C. A. Dye, of the College of Pharmacy, Ohio State University.

Dr. Patterson, editor of Chemical Abstracts, gave an address on the origin and history of our journal, "Chemical Abstracts," as well as the methods of handling the problems involved.

At the previous meeting Dr. John Wilkinson, of the Department of Chemistry, Ohio State University, read a paper on the "Phosphorescence of Some Inorganic Salts," and Dr. J. F. Lyman, Department of Agricultural Chemistry, read a paper on the "Experimental Study of the Metabolism of the Purins in the Mammalian Organisms."

The following officers were elected: *President*, C. W. Foulk; *Vice-President*, A. M. Brumbach; *Secretary-Treasurer*, James R. Withrow, Ohio State University; *Councilor*, Wm. McPherson.

JAMES R. WITHROW, *Secretary.*

UNIVERSITY OF MISSOURI SECTION.

The annual meeting of the Section was held on Friday, May 13th, at 7 P.M. Reports of officers were given and approved. The following officers were then elected for the coming year: *President*, Sidney Calvert; *Vice-President*, R. B. Gibson; *Secretary*, E. E. Morlan; *Treasurer*, Hermann Schlundt; *Councilor*, P. F. Trowbridge.

C. ROBERT MOULTON, *Retiring Secretary*

LOUISVILLE SECTION.

The regular May meeting of the Section was held in Lexington on the 14th, where the Louisville members were the guests of the Lexington members. The visitors were royally treated. The forenoon was spent in automobiling through the blue grass regions and at noon a dinner was served at the Country Club. The party then returned to the Chemical Building of the State University where the meeting was held. Election of the following officers first took place: *President*, R. C. Lord; *First Vice-President*, A. M. Peter; *Second Vice-President*, C. E. Martin; *Secretary*,

F. F. Hasbrouck; *Treasurer*, B. M. Overton; *Councilor*, F. E. Tuttle. Three papers followed: "Colloids," Dr. R. N. Maxson. "Theory of the Continuous Still," A. M. Breckler. "Kentucky Clays," J. S. McHargue. There were about 30 present.

F. F. Hasbrouck, *Secretary*.

PHILADELPHIA SECTION.

The regular May meeting of the Section was held at the Engineers' Club, Thursday evening, May 19th. The annual election of officers resulted as follows: *Chairman*, A. M. Comey; *Vice-Chairman*, C. H. Spayd; *Secretary-Treasurer*, C. S. Brinton; *Executive Committee*, George D. Rosengarten, William H. Bowers, D. W. Fetterolf.

The following papers were presented: "The Chemistry of the Suprarenal Gland," C. E. Vanderkleed. "Analysis of Ground Cloves," Arthur T. Collins.

Clement S. Brinton, *Secretary*.

CHICAGO SECTION.

The May meeting was held in the rooms of the Engineers' Club, on Friday, May 20th, at 8 P.M., with 125 in attendance.

The program for the evening was a "Symposium on Soap," including the following papers: "Special Points to be Considered in the Analysis of Soaps," by Wilson H. Low, Cudahy Packing Co., Omaha, Neb. "The Work of the Glycerine Committee of the American Chemical Society," by A. C. Langmuir, Marx & Ravolle, New York. "Glycerine Analysis," by Robert E. Divine, Detroit, Mich. "The Pears Soap Case: Detection of Volatile Substances in Soaps," by E. M. Slocum, Allen B. Wrisley Co., Chicago. "The Manufacture of Glycerine by the Garrigues Process," by G. A. Moore, Chicago. "Historical Review of Saponification Processes," by W. D. Richardson, Chicago.

The usual informal dinner took place before the meeting.

A L. Nehls, *Secretary*.

LOUISIANA SECTION.

The Section held its forty-first regular meeting in the rooms of the New Orleans Board of Trade, May 20th. Dr. B. P. Caldwell, of Tulane University, gave a lecture on "The Corrosion of Iron."

The 42nd meeting and annual dinner was held Friday, June 17th, 6.30 P.M., at the Old Hickory Restaurant. The topic for discussion was "Chemical Technology in Louisiana."

Geo. B. Taylor, *Secretary*.

KANSAS CITY SECTION.

The Section met at the Y. M. C. A. Building, Kansas City, Mo., on Saturday evening, May 21st at 5 o'clock. The following program was presented: "Chemistry and Cupola Practice," by W. W. Cox, and "Salt Rising Bread," by H. A. Kohman, after which dinner was served.

E. A. White, *Secretary*.

SECTION OF EASTERN NEW YORK.

The May meeting was held in the Union College Chemical Lecture Room, Schenectady, on Wednesday evening, May 25th, at 8 o'clock. A paper on "Accuracy in Certain Difficult Determinations" was presented by Prof. E. W. Morley, followed by refreshments.

The June meeting was held in Little Falls on the afternoon and evening of Saturday, June 11th.

In the afternoon visits were made to Hansen's Laboratory, where Junket tablets are made; to the plant of D. H. Burrell & Company, where milk separators and milking machines are manufactured, to the tannery of the Barnet Leather Company; and to "Overlook," Mr. D. H. Burrell's private residence. After dinner at Hotel Richmond, addresses were given as follows: "The Products of Milk," and the "Junket Tablet," by J. D. Frederiksen, of the Hansen Laboratory; and "Milking Machines and Milk Separators," by Loomis Burrell, of D. H. Burrell & Company.

K C ROBINSON, *Secretary*

RHODE ISLAND SECTION.

The regular meeting of the Section was held at the University Club, Thursday evening, May 26th. Dinner was served at 7 o'clock, following which Dr. Frederick G. Keyes, of Brown University, presented the paper of the evening, "Some Recent Researches in High Vacuum."

ALBERT W. CLAFLIN, *Secretary.*

WISCONSIN SECTION.

A joint meeting of the Milwaukee, Chicago and Wisconsin Section, was held in Milwaukee, May 27 and 28th. The program consisted of a smoker Friday evening, papers by members of the Sections Saturday morning, and a visit to certain technical industries Saturday afternoon.

E. V McCOLLUM, *Secretary.*

NEBRASKA SECTION.

The sixtieth regular meeting of the Section was held at Omaha, Nebraska, Saturday, May 28th. The Section assembled at the Rome Hotel and left by street car at 1.15 P.M. for the Carter White Lead Works in East Omaha, arriving at 2.00 P.M. Leaving there at 3.30 P.M., the members arrived at the Smelter at 4.15 P.M. and left at 5.30 P.M. At 6 P.M. dinner was served at the Rome Hotel. After dinner an address was given by Professor George B. Frankforter, Dean of the School of Chemistry, University of Minnesota, on "Utilization of Waste Wood with Some of its By-Products."

O. L BARNEBEY, *Secretary.*

CORNELL SECTION.

The 62nd regular and 8th annual meeting of the Section was held in Morse Hall, Wednesday, June 1st.

The program consisted of the following reports: "Fractional Crystallization of the Rare Earths," by C. W. Bennett. "Fractionation of the Rare Earths," by H. N. Frear. "Temperature Measurements in the Carborundum Furnace," by H. W. Gillett. "Electrolysis of Certain Liquid Ammonia Solutions," by M. E. Holmes. "Sugar and Alcohol in Apple Waste," by B. J. Lemon. "Sulphated Storage Cells," by G. A. Perley.

The following officers were elected for the ensuing year: *President,* H. W. Redfield; *Vice-President,* F. F. Shetterly; *Secretary-Treasurer,* J. C. Andrews; *Executive Committee,* G. E. F. Lundell, E. F. Hitch, L. J. Cross.

H. W. GILLETT, *Retiring Secretary.*

GEORGIA SECTION.

The Section held its spring meeting in the rooms of the Atlanta Club on the evening of June 4th. Unusual interest was manifested in the business and the papers. It was decided to meet more frequently, the programs subject to the decision of the advisory board. After the meeting the Section adjourned to the Rathskellar to discuss the papers over a Dutch lunch. The papers of the evening were: "The Volumetric Determination of Phosphoric Acid by Precipitation in the Cold," by W. P. Heath. "The Halides of Tantalum," by Walter K. Van Haagen. "Soil Fertility," by F. B. Porter.

J. S. BROGDON, *Secretary.*

NEW YORK SECTION.

The ninth regular meeting of the session of 1909–'10 was held at the Chemists' Club on June 10th.

The following papers were presented: Chas. Baskerville and W. A. Hamor, "The Examination of Ethyl Ether." H. C. Sherman, E. C. Kendall and E. D. Clark, "An Examination of Present Methods of Determining Diastatic Power." E. C. Kendall and H. C. Sherman, "A Study of the Action of Pancreatic Amylase." F. J. Pond, "A Case of Iron Corrosion." Arthur E. Hill, "A Note on the Constancy of the Solubility Product."

C. M. JOYCE, *Secretary.*

DECEASED MEMBERS.

George F. Barker, May 24, 1910, Philadelphia, Pa.
Stanislao Cannizzaro, May 10, 1910, Rome, Italy.
Franklin C. Robinson, May 25, 1910, Brunswick, Maine.

Proceedings.

COUNCIL.

MEMBERS ELECTED BETWEEN JUNE 15TH AND JULY 15TH.

Alanne, W. S., care Sampo Coal Co., Hanna, Carbon Co., Wyo.
Arbuckle Brothers, 71 Water St., New York City.
Arthur D. Little, Inc., 93 Broad St., Boston, Mass.
Baker, H. J. & Bro., 100 William St., New York City.
Bartow, Wm. R., 207 Oneida St., Utica, N. Y.
Benzinger, R., 1219 Chestnut St., Oakland, Cal.
Bernreuter, W., State Water Survey, Urbana, Ill.
Bouton, Craig M., Breckenridge, Colo.
Chemical Products Co., 93 Broad St., Boston, Mass.
Cook, Carl L., 77 Carl St., San Francisco, Cal.
Copes, Louis G., 1216 N. Frazier St., Philadelphia, Pa.
Dick, M. Everett, Holland, Mich.
Fuller, George P., 7 Alfred St., Medford, Mass.
Hammer, R. F., 807 W Church St., Champaign, Ill.
Johnston, W. Armour, Jr., Princes Bay, New York City.
Leeds, John J., care S. & L. Rubber Co., Chester, Pa.
Lester, Charles, 1664 Mance St., Montreal, P. Q., Canada.
Osgood, George D., Hopedale, Mass.
Paisley, John W., 477 West 145th St., New York City.
Perry, Cyrus W., 62 Pine St., Rutland, Vermont.
Peter Cooper's Fertilizer, 111 Broadway, New York City.
Phillips, Alex. W., care Sinnemahoning Powder Mfg. Co., Sinnemahoning, Pa.
Salomon, Ben L., 3020 Mt. Vernon Ave., Milwaukee, Wis.
Stock, G. M., 3610 Clifton Ave., Baltimore, Md.
Stoner, Wm. H., 534 E. Marshall St., Norristown, Pa.
Strauss (Miss) Anna B., 377 Woodlawn Ave., Buffalo, N. Y.
Strosacker, Charles J., Midland, Mich.
Swift, Thos. B., Martinez, Cal.
Vekander, Andrew, Box 547, Petaluma, Cal.

BOARD OF DIRECTORS.

A Directors' meeting was held at the Chemists' Club, New York City, at 8.30 P.M., June 24, 1910, with Directors Bancroft, Hallock, Parker, Love, Little and Parsons present.

It was voted to allow W. D. Richardson sixty dollars per month for clerical expenses while he continues in charge of the advertising and thirty dollars per month thereafter.

It was voted to instruct the Finance Committee to approve such bills as may be necessary to cover the printing of advertisements in the Journal of Industrial and Engineering Chemistry.

It was voted to add one hundred and fifty dollars to Back Number Account for the purpose of reprinting certain numbers of the Journal in

Vols. 3, 4 and 5 that were necessary to complete sets for which orders were already on hand.

In pursuance of a vote of the Council at Boston to the effect that the Directory of the Society be issued as a separate and that the Directors lay down conditions which shall properly safeguard the use of the list from those who wish it for advertising purposes, the Direotors voted as follows:

A. That a single copy of the list may be sent gratuitously to

1. Regular advertisers in our publications but only for their own use.

2. Officers or committees of the Society for Society purposes.

3. Other scientific, benevolent or educational societies in exchange for their own list where same is desired.

B. That on payment of twenty-five cents to cover cost of printing and mailing it may be sent to any member of the Society on signed application therefor stating that the member desires it for his own personal use and that he will not loan or dispose of it to any firm or to any other individual to be used for advertising purposes.

C. That it may be sold by the Secretary to any firm or individual for ten dollars.

It was voted that one thousand dollars be added to that portion of the Budget applying to the printing of Chemical Abstracts.

It was voted that the conditions for free advertisements in the Journal of the American Chemical Society for members seeking employment be changed so as to limit the amount of free insertion to a one-half inch space and to two consecutive insertions but that a third insertion might be allowed upon special request, the change to go into effect on September 1st.

It was voted that the price of Volume 3 of Chemical Abstracts be advanced to ten dollars to members and twelve dollars to non-members of the Society.

The Secretary was instructed to secure sample pages of the Journal of Industrial and Engineering Chemistry printed in 8, 9, and 10 point type for comparison to be submitted to the Directors at a later meeting in order that they might pass intelligently upon the subject referred to them by the Council.

The meeting then adjourned.

CHARLES L. PARSONS, *Secretary.*

MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons, Durham, N. H.]

PUGET SOUND SECTION.

The seventh regular meeting was held at the "Faculty Club House," University of Washington, Saturday, March 26th, at 6.30 P.M. Dr. Horace G. Byers addressed the Section on "Some Chemical Curiosities." After the address the Section visited the new chemical laboratories of the University of Washington.

The eighth regular meeting was held at the Engineers' Laboratory, City Hall, Saturday, May 28th, at 8 P.M. Mr. C. J. Moore, Assistant City Engineer, addressed the Section on "Some Notes on the Installation and Operation of the 60-Ton Refuse Destructor at Lake Union."

A. JACOBSEN, *Secretary.*

ST. LOUIS SECTION.

The regular June meeting of the Section was held on the 13th at the St. Louis Academy of Science Building. The subject for the evening was "The National Pure Food Law," which was extensively discussed both from a chemical and from an executive point of view by Mr. D. B. Bisbee, Chief of the Food Inspection Laboratory, St. Louis.

R NORRIS SHREVE, *Secretary.*

SYRACUSE SECTION.

The 59th meeting took place at Frenchman's Island, Oneida Lake, on Saturday afternoon, June 18th, in the following picnic fashion:

2.30 P.M. –Left for Frenchman's Island, *via* South Bay, arriving at 3.45.

4.00 P.M.—Ball game between the Has-Beens of the Halcomb Steel Works and the Never-Wases of the Solvay Process Co.

6.00 P.M.—Supper continuing, until provisions were gone.

7.00 P.M.—Formal installation of officers for ensuing year.

President, E. N. Pattee; *Vice-President*, F. E. Englehart; *Secretary*, W. H. McLauchlan; *Treasurer*, L. M. Fenner; *Nat'l Councilor*, J. D. Pennock.

8.00 P.M.--First detachment leaves for Syracuse.

W H McLAUCHLAN, *Secretary.*

DECEASED MEMBER.

Dr. Wm. H. Seaman, June 10th, Washington, D. C.

Stanislao Cannizzaro.

On May 10, 1910, the American Chemical Society lost by death one of its most distinguished foreign members, Stanislao Cannizzaro. He was born in Palermo, July 13, 1826, where his father was president of the High Court of Chancery. During the revolution of 1848 Cannizzaro, a youth of twenty-two, espoused the cause of the patriots and became a member of the Sicilian Parliament, and an officer of artillery. On the collapse of the Sicilian movement he managed to escape capture and found his way to Marseilles, and thence with the aid of friends to Paris.

He had already been an assistant in the laboratory of Piria, and Cahours now found him a place under Chevreul, where he worked in coöperation with Cloëz. In 1851 he was appointed to a professorship of chemistry at Alexandria in Piedmont; in 1855 he was called to a chair at Genoa, and thence in 1861 to Palermo, where he remained ten years. In 1871 he was transferred to the University of Rome and made a senator of the Kingdom, an appreciation of intellectual merit for which America can offer no equivalent. At Rome the remainder of his life, nearly forty years, was spent, and under his inspiration many of the most famous Italian chemists received their training.

In the great transition from the chemistry of the Berzelian period to the chemistry of to-day, Cannizzaro was perhaps the central figure. During the decade previous to 1858, chemical theory was in almost a state of chaos; nothing seemed to be settled, the noise of inconclusive controversies filled the air. In 1858, however, Cannizzaro published a "Summary of a Course of Chemical Philosophy" which completely changed the aspect of affairs. In this summary the modern system of atomic weights was proposed, which brought the Daltonian constants into harmony with the long neglected law of Avogadro, and the specific heat regularities discovered by Dulong and Petit. A new system of chemical formulae at once replaced the old; the theory of valence assumed shape; the ideas of chemists relative to constitution and structure were clarified. Modern chemistry was born the day that the summary was published, and soon grew into the vast philosophy of our own time. The change that Cannizzaro brought about made all the other changes possible.

Cannizzaro was not a voluminous writer, but his work more than made up in quality what it lacked in bulk. He was essentially an organic chemist. At Paris, with Cloëz, he began the study of the amines, and discovered cyanamide. Later, while at Alexandria, he discovered benzyl alcohol and worked on anisic alcohol with Bertagnini. Practically all of his later studies related to aromatic compounds, and especially to santonin and its derivatives. His active career as an investigator seems to have ended in 1896, when, with Andreocci, he published a research upon the constitution of dimethylnaphthol.

Cannizzaro was the recipient of many honors. He was elected into the great academies of the world, and had honorary membership in the American, British and German Chemical Societies. In 1891 the Royal Society of London gave him its highest recognition, the Copley medal. All these honors were well deserved, for the work of Cannizzaro marked an epoch in the history of chemistry. F. W. CLARKE.

Issued with the September Number, 1910.

Proceedings.

MINUTES OF THE FORTY-SECOND GENERAL MEETING OF THE AMERICAN CHEMICAL SOCIETY.

The meeting of the American Chemical Society in San Francisco and the sight-seeing and entertainments enjoyed there and en route will always be remembered by those who attended as one of the most pleasant memories of their lives.

The members taking the special train, some 110 in number, gathered at the La Salle Hotel in Chicago on July 4th, where they were entertained at luncheon as the guests of the Chicago Section.

The special train, furnished by the Santa Fe Road, was especially composed of the Pullman Company's finest equipment, electric-lighted throughout, with observation, library and buffet cars.

The first stop was made at Colorado Springs, where most of the members took the trip to Pike's Peak and to the Garden of the Gods, while others contented themselves with the attractions around Manitou and the Cheyenne Canyon.

On the following morning the train stopped for a short period only at Albuquerque and reached Adamana at 1 o'clock, where carriages and wagons were in waiting to take the party to the Petrified Forest, some twelve miles distant. Although the sun shone brightly, no inconvenience was experienced, owing to the altitude and the dryness of the atmosphere, and all were repaid by the wonders awaiting them.

The following afternoon, July 9th, was spent in driving around Redlands and in automobiling through the orchards and palm-grown avenues of Riverside. The party had already been met at the Grand Canyon by Mr. Ralph A. Gould, chairman of the local committee, welcoming them to the State of California on the part of the California Section, and just before reaching Riverside a committee of chemists from Los Angeles met the train and outlined the entertainment to be given by the Los Angeles chemists on the following day.

July 10th was spent in and around Los Angeles as guests of the local chemists, visiting Pasadena, the San Gabriel Mission and Long Beach, and dinner was served at a pleasant resort on the seashore. In the evening the visiting members were entertained with a reception and dinner at the Sierra Madre Club and retired at a late hour to the special train, awaking in the morning at Lang, California. Here the party became the guests of the Sterling Borax Company, visiting their mines on a special train provided for the purpose, and each member received an interesting souvenir of the trip.

That afternoon and evening were spent at Santa Barbara, where a carriage drive was taken and the Santa Barbara Mission visited.

Early the next morning as the party approached Salinas the greatest excitement of the whole trip was furnished by the wrecking of the special train, which ran off the track in rounding a curve, completely destroying the engine and three cars. Fortunately none of the party was seriously hurt, although those in the forward part of the train were severely shaken up. After about three hours' delay, the party proceeded to San José, where they were met by many members of the California Section and were entertained at lunch at the Vendome Hotel. Leaving again for San Francisco, the train was found full of bouquets of sweet peas and baskets of fruit presented to the ladies of the party by the San José Chamber of Commerce.

At 6 o'clock, July 12th, the party arrived in San Francisco and from that time on the hospitality of the California Section was boundless. Every detail had been attended to by the Local Committee. Each member was immediately taken to a taxicab, carried to his hotel, and special vans were waiting for the baggage, which, without any attention on the part of the visiting members, was soon found awaiting them in their rooms. On arrival at the hotel, ladies found bouquets of roses awaiting them.

On Wednesday morning, July 14th, the 42d General Meeting was called to order by President Bancroft in the St. Francis Hotel. After an address of welcome by Arthur Lachman for the California Section, responded to by President Bancroft, the following addresses were delivered in general session.

Positive Photography. Illustrated with lantern slides. W. D. Bancroft.

Liquid Ammonia as a Solvent and the Ammonia System of Acids, Bases and Salts. Edw. C. Franklin.

Chemistry in the Bureau of Standards. W. F. Hillebrand.

The Use of Sodium Benzoate as a Preservative of Food. H. E. Barnard.

At the same time a ladies' reception was held in the parlors of the St. Francis Hotel.

After luncheon the members present and their guests enjoyed an excursion over the Ocean Shore Railroad to Half Moon Bay and Tunitas Glen, returning in time for the smoker held in the Fairmont Hotel, and the ladies' theater party. A hot supper had been promised at the smoker and all who partook of the tamales and heard the Chinese music were ready to acknowledge that the adjective was quite descriptive.

On Thursday morning the meetings of the Divisions were held in the St. Francis Hotel, and many interesting papers were presented. The Symposium on Smelter Smoke before the Industrial Division excited special interest.

After luncheon all attending the meeting enjoyed one of the most pleasant excursions of the trip, made by special train to the top of Mt. Tamalpais and through the Muir Woods, and the members were entertained at a banquet during the evening on the top of the mountain. Several of the members remained all night, coming down the mountain on the following morning in gravity cars. This grove of redwoods, named after John Muir, is probably one of the most beautiful bits of scenery in the immediate vicinity of San Francisco, and the ride to the top of the mountain with the changing interest of foliage and panorama of hill, valley, bay and distant city of San Francisco was appreciated by all.

Friday morning was spent at the University of California in Berkeley, mainly in an examination of the various buildings, laboratories and campus of this beautifully-situated institution.

The party then took a special steamer as the guests of the Selby Smelting and Lead Company, being entertained at luncheon by the Company and afterwards conducted through their plant, where the various processes of lead smelting and the recovery of gold and silver therefrom were explained. One of the chief attractions of this plant was the opportunity given to view the new Cottrell precipitating apparatus installed for the purpose of removing sulphur trioxide and any other solids or liquids present in smelter smoke.

After returning to San Francisco, the evening was spent in a visit to Chinatown, where at 10 o'clock all were entertained at a Chinese collation of tea and sweets served in a Chinese restaurant to music which the Local Committee characterized as sweet.

Saturday morning was devoted to divisional meetings at which the remaining papers on the program were read.

In the afternoon at 2'oclock the members were treated to an automobile ride over Buena Vista Heights, through the Golden Gate Park to the ocean beach and the Cliff House, returning through the Presidio and the residential section of San Francisco.

In the evening the members all assembled for the main banquet of the week in the St Francis Hotel, at which all of the ladies attending were guests. About 250 sat down to the banquet, which will long be remembered by all present.

On July 17th, the party, as the guests of the Italian-Swiss Colony, took a special train to Asti, where an unusually pleasant day was enjoyed in examining the vineyards and wineries of this well-known section. The lunch was served outdoors in unusually attractive pergolas. The party returned to San Francisco early in the evening and were given, almost for the first time, opportunity to sleep.

On the following morning, July 18th, an excursion was taken by steamer up the Sacramento River to Sacramento through the wonderfully fertile fields of the Sacramento Valley, between levees so high that the party was obliged to view the country from the upper deck of the steamer. The general aspect was much like that of portions of Holland. Returning from Sacramento by train, the party reached San Francisco late in the evening, having been royally entertained. Many, however, took train at Sacramento for the north.

On Tuesday, July 19th, a special steamer was provided for those who remained to visit and examine the various points of interest around San Francisco Bay.

Following the meeting in San Francisco, the members returned to their homes by various routes, but some thirty traveled northward by invitation of the Puget Sound Section to visit Seattle and obtain a view of the Northern Pacific Coast scenery. Arriving in Seattle on the morning of the 21st, the party was met by President Falkenburg, of the Puget Sound Section, Horace G. Byers, Councilor of the Section, President Kane, of Washington University, and others, who welcomed them as the guests of the Puget Sound Section.

On arrival the ladies were supplied with bouquets of dahlias, and shortly afterwards all started on an automobile trip which covered all parts of the city, both business and residential, and included the beautiful grounds of Washington University.

At the end of the drive the party was lunched at the Commercial Club, after which they immediately left on a chartered steamer for a trip around Puget Sound. The first stopping-point was the plant of the Pacific Creosoting Company, where the party left the boat and inspected the largest creosoting plant in the world. Returning, a stop was made at the Navy Yard, where battleships and armored cruisers were examined, and then the party proceeded to Tacoma, where a delightful lunch was served under the enormous trees of the Tacoma City Park. By the courtesy of the Board of Park Commissioners, the party was well supplied with roses and given permission to pick all the sweet peas they could carry away.

From Seattle some of the party came east *via* Vancouver and the Canadian Rockies, while others came over the Northern Pacific, visiting the Yellowstone National Park.

Unusual enthusiasm was shown throughout the whole meeting and many new western members were added to the Society, which now has a membership of over five thousand.

290 members and guests registered for the meeting.

120 papers were presented at the meeting embodying new chemical research, many of them reporting very important results.

The programs presented before the various divisional meetings were as follows:

Division of Agricultural and Food Chemistry.

The minutes and program of this Division will be found in the *Journal of Industrial and Engineering Chemistry.*

Division of Industrial Chemists and Chemical Engineers.

A special feature of the program was the Symposium on Smelter Smoke, opened by the following three papers:

The Smoke Problem and the Community. Charles Baskerville.
The Neutralization and Filtration of Smelter Smoke. W. C. Ebaugh.
The Electrical Precipitation of Suspended Matter. F. G. Cottrell.

Details in regard to this symposium and the remainder of the papers presented before the Division will be found in the August number of the *Journal of Industrial and Engineering Chemistry.*

Division of Physical and Inorganic Chemistry.

The following papers were presented to the Division:

Further Studies on the Action of Ammonia upon Ethylphospho-platino chloride. Chas H. Herty and Hamden Hill.

Stratification in Suspensions. F. K. Cameron and E. E. Free.

The Rate of Consolidation of Kaolin Precipitates. F. K. Cameron and E. E. Free.

The Action of Alkalis on Kaolin Suspensions. F. K. Cameron and E E. Free.

The Temperatures of the Carborundum Furnaces. Wilder D. Bancroft.

Salvaging Sulfated Storage Cells Wilder D. Bancroft.

The Silver Coulometer. G. D. Buckner and G. A. Hulett.

Occlusions in Electrolytic Silver. J. S. Laird and G A. Hulett.

An Exact Electrolytic Method for Determining Some Metals W. L. Perdue and G. A. Hulett.

Cadmium Sulphate and the Atomic Weight of Cadmium. W. L. Perdue and G A. Hulett.

Equilibrium in the System KI, I and Aqueous Alcohol. C. L. Parsons and H. P. Corliss.

The Solubility of Barium Nitrate in Solutions of Barium Hydroxide. C. L. Parsons and H. P. Corson.

The Solubility of Strontium Nitrate in Solutions of Strontium Hydroxide. C. L. Parsons and C. L. Perkins.

A Common Thermometric Error in Determining Boiling Points under Reduced Pressure. Alexander Smith.

A Convenient Form of Vapor Density Apparatus. Alan W. C. Menzies.

Basic Nitrates of Yttrium. Chas. James and L. A. Pratt.

The Systems, Lime-Water-Sugar, and Lime-Water-Glycerine at 25° C. F. K. Cameron and H. E. Patten.

Phosphates of Lime, IV. F. K. Cameron and J. M. Bell.

Heats of Neutralization in Non-aqueous Solutions. J. Howard Mathews.

Comparative Analyses of Water from Great Salt Lake. Wallace Macfarlane.

A Suggestion for Instructors in Quantitative Analysis. W. C. Ebaugh.

A Reported Occurrence of Native Iron. W. C. Ebaugh.

Improvements in Molecular Weight Determinations by the Boiling Point Method. L. B. Shipley and J. O. Ziebolz.

The Influence of Organic Liquids upon the Interaction of Hydrogen Sulfide and Sulfur Dioxide. David Klein.

Some Interrelations of the Carbide and Nitride of Magnesium. F. G. Cottrell.

Determination of the Vapor Pressure of Slightly Volatile Solids. H. V. Welch.

Preparation of Pure Anhydrous Ethyl Alcohol. E. C. McKelvy.

Rapid Determination of Mercury, Silver, Bismuth and Copper by means of Stationary Electrodes. R. C. Benner.

The Atomic Weight of Tantalum. Clarence W. Balke.

Concerning the Molecular Weight of Sulphur Vapor. O. F Stafford.

A Rotating Graphite Anode. J. W. Turrentine.

Apparatus for the Determination of Arsenic. Otis D. Swett.

Behavior of Certain Hydrazine Salts in Liquid Ammonia. A W. Browne and A. E. Houlehan.

Electrolysis of Solutions of Potassium Amide and of Ammonium Trinitride in Liquid Ammonia. A. W. Browne and M. E. Holmes.

Electrolytic Corrosion of Various Metallic Anodes in a Solution of Ammonium Trinitride in Liquid-Ammonia. A. W. Browne, M. E. Holmes and J. S. King, Jr.

The Examination of Ethyl Ether: (*a*) A Study of the Tests for Odor, Residue, Acidity and Sulphur Compounds in Ethyl Ether (*b*) The Tests for the Presence of Water and Alcohol in Ethyl Ether. (*c*) On the Changes Occurring in Stored Ether and on the Existence of Ethenol in Ethyl Ether (*d*) The Tests for the Presence of Peroxides and Acetaldehyde in Ethyl Ether. (*e*) On Some New Tests for the Detection of Peroxides in Ethyl Ether. (*f*) The Examination of Ethyl Ether intended for Anesthetic and Reagent Purposes; the Degrees of Purity of American Ethers, and Recommendations for the Standardization of Anesthetic Ether. Charles Baskerville and W. A. Hamor.

Mechanical Stimulus to Crystallization. S. W. Young.

Zinc Ammonium Sulfate. Eloise Jameson.

The Viscosity of Liquid Ammonia, Sulfur Dioxide and Methyl Amine F. F Fitzgerald.

Electrical Conductivity of Solutions in Methyl Amine and Ethyl Amine. F. F Fitzgerald.

Conductivity of Some Solutions in Ammonia Water Mixtures. Wm. H. Sloan.

Cuprous Nitrate. Wm. H. Sloan.

Potassium Ammono-plumbite; Potassium Ammono-cobaltate; Potassium Ammono-nickelate. E. C. Franklin and G. S Bohart.

Chemical Valence and Atomic Charge. Fernando Sanford.

Division of Organic Chemistry.

The Division was presided over by Professor Moses Gomberg acting for President E. C. Franklin, and H. C. Biddle was elected Secretary. A memorial of Dr. H. A. Torrey, a member of the Executive Committee, was read and ordered recorded in the minutes. The following papers were presented to the Division.

1. Action of Acetic Anhydride on *p*-Methoxy Phenyl Propiolic Acid and on Methylene Ether of 3-4 Dihoxy Phenyl Propiolic Acid. Maurice L. Dolt.

2. The Constitution of the Oxonium Salts. M. Gomberg.

3. Action of Amines on Phthalic Acid, VII. Phthalamidic Acids Containing Cl or NO_2 in the Benzene Nucleus. J. Bishop Tingle and S. J. Bates.

4. Camphoroxalic Acid, XIII. Action of Amines on Camphoroxalic Acid. J. Bishop Tingle and S. J. Bates.

5. Stilbazoles in the Quinazoline Group. M. T. Bogert and G. D. Beal.

6. Isocampholactone. W. A. Noyes and A. W. Homberger.

7. Separation of a,a-Dimethyl Adipic Acid into its Optical Isomers and the Synthesis of Laurolene. W. A. Noyes and L. P. Kyriakides.

8. Derivatives of Isocamphoric Acid. W. A. Noyes and Luther Knight.

9. Decomposition of Nitrosophthalalimidine in the Presence of Alcohol. W. A. Noyes and James A. Coss.

10. Conversion of Quinine into Quinotoxime. H. C. Biddle.

11. Metathetical Reactions, Ethyl Thioureas and their Relation to Pseudo-ammonium Bases.

12. The Unsaturated Character of the Resin of *Pinus Sabiniana* Chas. H. Herty and E. N. Tillett.

13. A Study of the Resene of *Pinus Heterophylla.* Chas. H. Herty, W. A. Houck and T. P. Nash.

Numbers 1, 2, 7, 8, 10, 11, 12 and 13 were read and discussed while the others were presented by title only.

Division of Pharmaceutical Chemistry.

The minutes and program of this Division will be found in the *Journal of Industrial and Engineering Chemistry.*

CHARLES L. PARSONS, *Secretary.*

COUNCIL MEETING.

The meeting of the Council was called to order by President Wilder D. Bancroft at 9 o'clock, July 12th, in the Green Room of the St. Francis Hotel, with the following members of the Council present: W. D. Bancroft, C. L. Parsons, C. H. Herty, G. B. Frankforter, A. P. Hallock, F. K. Cameron, F. B. Porter (for W. P. Heath), A. M. Comey (for W. T. Taggart), A. M. Patterson, H. E. Barnard, Felix Lengfeld, H. McCormack (for W. R. Smith), W. L. Dudley, W. F. Hillebrand, G. P. Adamson, W. R. Whitney, C. F. Crowley (for S. Avery), Alex. Smith, W. A. Noyes, H. G. Byers, L. H. Baekeland, F. E. Gallagher (for H. J. Skinner), and M. Gomberg.

Letters from absent members and others, addressed to the Council' were read by the Secretary.

Chairman W. F. Hillebrand, of the Committee on Standard Methods of Analysis, presented a report in regard to the organization of the various committees engaged in standardizing methods of analysis. He stated that owing to the confusion and duplication which had already begun to creep into the work of the General Society and its various Divisions, extensive conferences had been held with the President of the Society, the chairmen and members of the central committee, the chairmen of the Industrial and Fertilizer Divisions and the divisional committees and others and as a result thereof a working scheme had been evolved which was seemingly satisfactory in principle to all who had taken part in the correspondence. He presented full lists of the various committees and showed wherein the duplication and confusion was arising and after careful and thorough discussion by the Council the following resolutions were unanimously adopted for the future government of these committees:

Resolutions Governing Committees of the American Chemical Society, and of Its Divisions, Having to do with the Standardization of Methods of Analysis.

1. Resolved, The name of the Committee on Standard Methods of Analysis (formerly Committee on Uniformity in Technical Analysis) shall be hereafter Supervisory Committee on Standard Methods of Analysis.

The nucleus of the committee shall consist of four members who are not chairmen of subordinate committees. In addition the chairmen of all committees in any way subject to its control shall have the right to deliberate and vote with the committee in all matters concerning the work of their respective committees, and on such additional matters as may be hereinafter specified, and they shall be to such extent members of the committee.

The Supervisory Committee shall remain, as heretofore, under the control of the Council of the Society, but shall be a committee with power.

Nominations to fill vacancies in the nucleus of the committee shall emanate from the full committee and shall be transmitted through the President to the Council for action at a regular meeting, except that an interim appointment may, on request from a majority of the full committee, proceed from the President.

In case of lack of agreement by the committee the President shall himself present nominations to the Council and may, in such case also, make interim appointments on his own responsibility.

2. Resolved, That the functions of this committee shall be as follows:

(*a*) To exercise control of the work of all subordinate committees, to the extent of preventing duplication of work and securing consistency in the form of publication of reports.

(*b*) To examine all reports of divisional or other committees in any way subject to it that are in any way final in the sense of recommending methods or parts of methods for general use. This involves the right to reject entirely such reports or to return them to the committee from which they emanate for such revision as may seem called for. It is assumed that no unduly arbitrary action will be taken in either of these directions, but that any decision rendered will be with a view to uphold the reputation of American chemists and the dignity of the American Chemical Society under whose sponsorship the reports may be published eventually.

3. Resolved, That on passage of the foregoing resolution the existing subcommittees of the central committee that is charged with the investigation of soaps and soap products pass at once, as now constituted, under the control of the Industrial Division, and that the present subcommittee on phosphate rock cease to exist as such, and that its accumulated data be placed by its chairman at the disposal of the corresponding committee of the Fertilizer Division.

4. Resolved, That the foregoing resolution does not abrogate the right of the Supervisory Committee to appoint special subcommittees on lines of work not represented by Divisions of the Society, these subcommittees to be responsible as in the past wholly to the Supervisory Committee.

5. Resolved, That divisional committees having to do with methods of analysis, including that transferred by Resolution 3, shall have full power under the control of their respective Divisions, to initiate and prosecute work, and to publish reports of progress.

Final reports, however, or such as recommend methods or parts of methods, for general use, shall be submitted by the chairman of the divisional committee to the Supervisory Committee for special consideration. Only on approval by this committee, except as hereinafter provided for, may such reports be published, subject to the usual submission to the Board of Editors of one or another of the Society's publications.

If the Supervisory Committee fail within three months to approve or reject a report submitted to it, the President of the Society (acting with the advice of the editors-in-chief of the Society's publications, and of the chairman of the Division concerned) shall be the final judge of its disposition. Acceptance or rejection by the Supervisory Committee within the time limit shall be final.

6. Resolved, That final reports, if published, shall appear as emanating from the particular Division or subcommittee concerned, with the approval of the Supervisory Committee (or of the President of the Society in lieu of approval by the Supervisory Committee as called for in the foregoing resolution), and that they shall be signed by or appear under the name of a majority of the committee under whose supervision they shall have been prepared.

7. Resolved, That the Divisions of the Society may in their judgment appoint either general committees vested with power to appoint and control subcommittees within the Division, or separate coördinate committees for different kinds of work, but in the former case only the chairman of the general committee shall have the restricted membership in the Supervisory Committee set forth in Resolution 1.

8. Resolved, That the chairmen of all divisional committees of first rank shall, before a given line of work is undertaken, notify the chairman of the Supervisory Committee of the character and scope of the contemplated work, in order that duplication by different Divisions may be avoided. In case of impending duplication and subsequent inability of the Divisions interested to come to an agreement the matter shall be decided by the Supervisory Committee.

In order to aid the chairman of the Supervisory Committee in the preparation of his annual report to the Council, the chairman of all divisional committees of first rank, and of special committees not under control of Divisions of the Society, shall each year upon call submit to him a brief report of work in progress or about to be undertaken in their respective committees.

Said chairmen shall further report to the chairman of the Supervisory Committee at the earliest possible moment the correct names of their own committees and subcommittees with a list of their members, and shall notify him of all changes made.

9. Resolved, That joint committees of this Society with other societies, shall report to the Supervisory Committee on Standard Methods of Analysis in the same way as has been prescribed in Resolutions 5 and 8 for divisional committees, and that the senior member by appointment from the American Chemical Society shall have the same rights and privileges in the Supervisory Committee as a chairman of a divisional committee.

10. Resolved, That in endeavoring to promote improvement in analytical methods the American Chemical Society does not contemplate making the use of such methods as may be recommended by its committees obligatory on any one, and, further, that no method recommended is to be considered as final, but simply as representing the best that can be done at the stated time. It is expected, as a matter of course, that revision will be exercised as knowledge and experience grow.

11. Resolved, That all previous resolutions conflicting in part or wholly with the foregoing Resolutions 1–10, are hereby repealed.

The Council voted to appoint a Committee on Chemical Museum as requested by the New York Section, and President Bancroft appointed Morris Loeb, Chairman, Victor Coblentz, Moses Gomberg, Jacob Hasslacher and Ralph H. McKee.

A letter was presented from Professor W. R. Orndorff in regard to the 60-day rule, and the Council instructed the Secretary to inform Professor Orndorff that the rule was essential to the proper conduct of the Society and could not be abrogated.

It was voted to hold the winter meeting, 1910–'11, at Minneapolis at the same time as the meeting of the American Association for the Advancement of Science.

Several invitations for the summer meeting of 1911 were presented to the Council and after careful discussion of the matter it was voted that the summer meeting for 1911 should be held in Indianapolis, the date for the same being left to the President and the Secretary with power.

The committee appointed to consider the publication of a new Journal of Agricultural and Food Chemistry reported progress and their opinion that it would not be possible to start such a journal before January, 1912. It was voted that an extension of time be granted to the committee, which would report again at the next annual meeting.

It was voted that the Council of the American Chemical Society endorsed the creation of a National Department of Health and that a committee be appointed to draw up suitable resolutions to be presented to the proper authorities. President Bancroft appointed Edw. C. Franklin, Charles F. Crowley and H. E. Barnard.

Communications were read from Mr. H. L. Taylor, of the Educational Department of New York State, in regard to the formation of a joint committee on spelling with other associations in order that greater uniformity in chemical spelling might be adopted. After discussion the Council voted that the matter be referred with power to the Board of Editors of the Journal of the American Chemical Society to confer with the committee mentioned by Mr. Taylor and to proceed as circumstances may warrant.

An application being received from twenty members in good standing, as required by the Constitution, it was voted to grant a charter to a new Section to be formed in territory within a radius of seventy miles of Pullman, Washington, said charter to become effective when a descriptive geographical name for the Section was decided upon. The Secretary was authorized to pass upon the matter for the Council.

The by-laws of the Pharmaceutical Division, passed by the Division at the Boston Meeting, were approved by the Council.

It was voted to accept the invitation of the Supervisory Board of the *American Year Book* to appoint a member of that Board representing the American Society, and the Council voted that the Secretary be designated as such.

The Council directed the Secretary to extend the thanks of the Council and the Society to the Chicago Section and the committee in charge of the entertainment at the La Salle Hotel; to the Los Angeles members through the committee appointed to represent them; to the Sierra Madre Club; to Mr. S. T. Mather and the Sterling Borax Company; to the San José Chamber of Commerce; to Ralph A. Gould, S. W. Young, Felix Lengfeld, W. C. Blasdale, F. T. Green, B. S. Drake, A. A. Hanks, Arthur Lachman and the committees of which they were chairmen; to the California Section; to P. C. Rossi, President of the Italian-Swiss Colonies; to Mr. E. B. Braden, of the Selby Smelting and Lead Company; to the Puget Sound Section and the committee representing them, for the overwhelming hospitality that has already been outlined in the general Proceedings.

By request of the President of the Second National Conservation Congress, President Bancroft has appointed to represent the American Chemical Society in that Congress: G. B. Frankforter, Marston T. Bogert, C. F. McKenna, F. G. Cottrell, W. C. Ebaugh.

The meeting then adjourned.

CHARLES L. PARSONS, *Secretary*.

MEMBERS ELECTED BETWEEN JULY 15TH AND AUGUST 15TH.

Agraz, Juan S., 6ª del Cipres 176, City of Mexico, Mexico.
Akers, Harry G., 447 Jarvis St., Toronto, Canada.

MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L Parsons, Durham, N. H.]

MINNESOTA SECTION.

The 27th regular meeting was held in the Chemical Laboratory of the University of Minnesota, on Friday evening, May 20th, at 8 P.M. Committees for the meeting of the Society next winter were announced, and the following program was rendered: "The Diffusion of Oxygen Through (*a*) Organic Liquids, and (*b*) Solids." G. B. Frankforter, G. W. Walker, and R. S. Callaway. "Influence of Traces of Iron, Lead and Copper on the Color of Cadmium Sulphide," G. B. Frankforter and J. G. Dietrichson.

FRANCIS C. FRARY, *Secretary*.

PHILADELPHIA SECTION.

The regular meeting of the Section was held at the Chemical Laboratory of Swarthmore College on June 16th and was preceded by the regular dinner, served in the Library of the College. The program consisted of an address by Dr. Edgar F. Smith, of the University of Pennsylvania, on "Modern Electro-Chemical Analysis," illustrated by experiments. The attendance was unusually large.

C. S BRINTON, *Secretary*

NORTH CAROLINA SECTION.

The summer meeting of the Section was held in the Agricultural Building at Raleigh on Wednesday, June 22nd, at eleven o'clock A.M. After a brief business session the following program was presented. Report: "Colloidal Chemistry," by Duncan MacRae. "The Unsaturated Character of the Resins of *Pinus Sabiniana*," by C. H. Herty and E. N. Tillett. "The Specific Heat of Benzol and Its Saturated Vapor," by J. E. Mills and Duncan MacRae. "The Bleaching of Flour by Nitrogen Peroxide," by W. M. Allen, State Food Chemist. "The Effect of Acids on Ethyl-Phospho-Platino-Chloride," by C. H. Herty and Hampden Hill. "The

Specific Heat of Carbon Tetrachloride and Its Saturated Vapor," by J. E. Mills and Duncan MacRae. "A Study of the Resene of *Pinus Hetrophylla*," by C. H. Herty, W. A. Houck and T. P. Nash.

BURTON J. RAY, *Secretary*.

MILWAUKEE SECTION.

The annual meeting of the Section was held on June 24th, at the Hotel Blatz. There was not formal program but a "Kneippe" was held. The following officers were elected for the ensuing year: H. W. Rohde, *Chairman*; F. S. Low, *Vice-Chairman*; Ben L. Salomon, *Secretary*; E. V. Manuel, *Treasurer*; George N. Prentiss, *Councilor*.

The Milwaukee Section held an informal meeting at Whitefish Bay on August 12th. Matters of interest and the policy and welfare of the Section for the coming year were discussed.

BEN L. SALOMON, *Secretary*.

RHODE ISLAND SECTION.

The annual meeting and excursion was held on June 25th, the trip this year being to the mines of the Rhode Island Coal Co., at Portsmouth. Dinner was served upon arrival, and the mines were visited immediately after the annual meeting following the dinner.

ALBERT W. CLAFLIN. *Secretary*

Issued with the October Number, 1910.

Proceedings.

COUNCIL.

MEMBERS ELECTED BETWEEN AUGUST 15TH AND SEPTEMBER 15TH.

Alexander, James, 2208–15th St., Walbrook, Baltimore, Md.
Anderson (Mrs.), A.M., Univ. of Chicago, Chicago, Ill.
Blakstadt, Ragnvald, Stortingsgaden 10, Kristiania, Norway.
Buckborough, S. A., Evanston, Ill.

Albert E. Leach, Aug. 22nd, Denver, Colo.

George Frederic Barker.

When the writer of the following paragraphs began the study of chemistry in 1872, his text-book was an "Elementary Chemistry" then in its tenth edition, written by the subject of this article. At the time the writer never dreamed that he was to become a colleague of this distinguished scientist, nor did it occur to him for a moment that at a later period he would be called upon to write in memory of this splendid teacher, profound student, and man of noblest character.

The face of Dr. Barker was quite familiar to men of science, both in this country and abroad, as he made it a point, when at all possible, to meet together with his fellows in science, thereby endearing himself to a wide circle of sympathetic friends, who, in recent years, have keenly felt his absence from their meetings, and were, indeed, shocked when the message of his death was announced. It was my privilege to meet Dr. Barker daily for many years, not so intimately at first, but later with the greatest freedom, and in true companionship. The impression made by him, at all times, was that of an earnest student of science, thoroughly conversant with its most recent advances and able, in a marked degree, to render what ordinarily seemed dry and unattractive, but extremely important, so simple and so fascinating, that the most ordinary layman might comprehend with ease. His lectures to students were celebrated for their clarity of presentation, as well as for their wide scope. He delighted in experiments, and one of his chief joys was to illustrate his lectures, as far as possible, with an abundance of attractive and striking experiments. The most intricate topics were presented before large audiences, reaching sometimes into the thousands, concisely and clearly, and so brilliant were his successes that he became noted throughout the country as one capable of popularizing science as few could do it. The writer recalls an occasion in his younger days, when the Academy of Music in Philadelphia was filled to its dome with an intensely interested and intelligent audience assembled to listen to Dr. Barker's lecture on "Sound," and, while seated in the "sky parlor" of the immense auditorium, enjoying the discomforts peculiar to his altitude at the moment, so intensely absorbing was the lecture and its experiments that at the conclusion it was difficult for him to realize that he had actually sat there more than an hour as an auditor.

As previously remarked, Dr. Barker's interest in his fellow men won for him hosts of friends, among whom were a number of the most eminent scientists of his day. Gladly did they present him with mementoes of their friendship, which he carefully cherished and joyfully exhibited to friends and students upon all proper occasions. In all gatherings he was a central figure. His affability and his courtesy were marked characteristics.

He was most deeply esteemed in the community where he lived by persons of all ranks. For a number of years he served on the Board of Education in the city of Philadelphia, and there exerted an influence which was entirely for the good, and never to be forgotten.

As a teacher he was painstaking in the presentation of his subject. It was a matter of conscience with him to have his students grasp and understand the problems he placed before them. He would go to any trouble to make abstruse points clear, and while at times he seemed to demand almost too much and be a bit brusque, yet no earnest student was ever turned away. The sincerity of the inquirer always led him to cast aside time, labor and comfort. Indeed, he was the true teacher, whose sole object was the welfare of those whom he taught.

At various times he appeared as an expert in scientific matters, and in this field further demonstrated his spirit of careful investigation, and absolute integrity and loyalty, as well as ability to be just and fair to all. Many of the cases involved the highest scientific knowledge and accuracy, which were abundantly supplied by him.

By his colleagues in the teaching staff of the University of Pennsylvania, he was most highly esteemed. His services were constantly engaged upon committees, and those who worked with him in such duties entertained but one impression,- to wit, that he was capable of handling the most intricate and perplexing problems with fairness, calmness and the best judgment. Indeed, it was a pleasure to be associated with him in work of this description. As a younger colleague, who profited so much by association with Dr. Barker, I cheerfully record my indebtedness to him for the most hearty coöperation and for his many helpful suggestions in the solution of the problems which fell to me. Dr. Barker was absolutely free from many of the littlenesses of character which so often mar the record of men of science and scholarship. It was a pleasure to place before him any little piece of work that one might be doing, for his mind was ever alert and open to new things, while he was always ready with an encouraging word or helpful suggestion.

His early academic training was received in the Boston Public Schools, and at the Academy in South Berwick, Maine. He further served an apprenticeship with Joseph Weightman- a maker of scientific apparatus, going thence to Yale where he was assistant in chemistry before graduation from the Sheffield Scientific School of that University in the year 1858. He was deeply attached to his Alma Mater, and invariably spoke in the highest praise of his early teachers. Indeed, for some of them his regard verged upon worship. His serious student days had, however, a bit of the modern in them, for if the writer remembers correctly, he was a member of the 'Varsity crew in the year of his graduation. Some years later in the autumn of 1869 he became Professor of Physiological Chemistry and Toxicology in the Medical School. Indeed, the chair was created for him. During this period, he served as expert for the State in several poison cases, the most noted being the Lydia Sherman case in New Haven. While lending to his colleagues such assistance as was possible, he was active scientifically. Thus, the *American Journal of Science*, **43**, 252, second series, contains a brief article "Upon the Silvering of Glass," which is a modification of a suggestion of Böttger.

Again, there appeared an article entitled "Account of the Casting of a Gigantic (Rodman) Gun at Fort Pitt Foundry," *Am. J. Sci.*, **37**, 296 (1863), which is really a letter from Dr. Barker to the editors of the journal upon a topic which, at the time, was attracting much attention.

A most interesting contribution is made, in the same journal (second series, 44, 263 (1867)), by Dr. Barker in support of the view that formic acid is carbonous acid. He believed this to be true because of the ready formation of formic acid by the partial oxidation of carbon, and also because it resulted from the reduction of carbonic acid. For these reasons he further concluded that formic acid was the acid of bivalent carbon.

Shortly after he contributed an extended communication "On Normal and Derived Acids," *Am. J. Sci.*, second series, 44, 384. He endeavored in this to aid in the establishment of a rational nomenclature.

In 1870 appeared his text-book of "Elementary Chemistry, Theoretical and Inorganic," which ran through many editions as well as translations into other languages and was the first book in our language wherein modern chemistry is presented systematically. The style of the book, as so many can testify from its study, is concise and clear. Wolcott Gibbs spoke of it as "a book wholly in the spirit of the most advanced thought in the science," but it may be added that Dr. Gibbs took some exception to the nomenclature employed by Dr. Barker, for he said that "such terms as potassium chlorate, calcium phosphate, etc., ... are, to say the least, of doubtful etymological propriety, and we greatly prefer the adjective form—potassic chlorate, calcic phosphate, etc."

A translation of Meissner's "Researches upon Electrolyzed Oxygen," was published by him in the *Am. J. Sci.*, second series, 1, 213.

During his sojourn at New Haven, he contributed a note "On the Spectrum of an Aurora which Appeared at New Haven, November 9, 1871." The point of particular interest in this observation was the fact that the line of wave length, 502, was not laid down in any authority accessible to the observer, as having been noted in the aurora spectrum. He adds: "Indeed, no previous observer, so far as I know, has seen any auroral line between the Frauenhofer lines *b* and F" (*Amer. J. Sci.*, third series, 2, 465 (1871)).

Some time later, he presented a second contribution "On the Spectrum of an Aurora of October 14, 1872." This aurora, like the one observed in 1871, was distinguished by its radiant crimson color, and by its form. Dr. Barker remarks that in the lines that appeared in the spectrum, none were new, though no previous observer had seen all of them at once. Vogel had seen five, and four had been seen by Dr. Barker. Two of the lines coincided nearly with the solar lines F and G, but a considerable difference was observed between the spectrum of this aurora and that of 1871, for three lines of the aurora of 1872 had no corresponding lines in the spectrum of the aurora of 1871.

Dr. Barker was assistant to Dr. Bacon in the Harvard Medical School from 1859–1861; Professor of Chemistry in Wheaton College, Illinois, 1861; then in the Albany Medical College, where he won the degree of Doctor of Medicine (1862–1863), making while there a chemical examination of the viscera of a dead body, the first time this had ever been done in this country; next, in the University of Pittsburg (1863); he also delivered the lectures on chemistry at Williams College in the years 1868 and 1869, and after service in his Alma Mater, to which reference has already been made, he became Professor of Physics in the University of Pennsylvania (1872) where the remainder of his life was spent. At this period he published a contribution of considerable length, with illustrations, on "A New Vertical Lantern Galvanometer," in which claim is made for the general principles of construction of the instrument, and the advantages possessed by it in the readiness with which it could be put into use, the brilliancy of the illuminated circle of light which it gave upon the screen, its great range of delicacy by which all experimental requirements might be answered, and, finally, the satisfactory character of its performance as a demonstration galvanometer (*Proc. Amer. Phil. Soc.*, **14**, 440).

This was followed by a communication "On the Measurement of Electromotive Force" (*Proc. Amer. Phil. Soc.*, **20**, 649) in which he described a form of Daniel cell in which the zinc sulphate and copper sulphate solutions were kept separate by closing a stopcock when the cell was not in use.

In 1880, before the American Association for the Advancement of Science, at its Boston meeting, Dr. Barker, as retiring president, delivered an address upon "Some Modern Aspects of the Life-Question."

In following the career of our friend there is plainly seen a versatility on his part, as well as a keen interest for other branches of science than that one to which he gave the best years of his life. Thus, he is found a member of an expedition to Rawlings, Wyoming, for the purpose of reporting "On the Total Solar Eclipse of July 29, 1878." His particular duty was to observe with an analyzing spectroscope the presence, either, of light or of dark (Fraeunhofer) lines in the spectrum of the corona.

Again, in connection with Professor Rowland, he reported "On the Efficiency of Edison's Electric Light" (*Am. J. Sci.*, third series, **19**, 337). Dr. Barker was the first to exhibit radium in this country (1899), after its isolation by Madam Curie in Paris, and radioactivity appealed so strongly to him, that it is not surprising to find "Radioactivity of Thorium Minerals" in the *Am. J. Sci.*, fourth series, **16**, 161. In this communication, the author introduces a number of original observations.

A very instructive address upon "Radioactivity in Chemistry" was delivered by Dr. Barker before the Chemical Society of Columbia University. It appeared in full in the *School of Mines Quarterly*, **24**, 267. It has historical value, and will prove extremely helpful to all wishing to familiarize themselves with the subject. It is accompanied with bibliographies covering 90 titles by the most prominent investigators in this particular field of research.

In 1899, Harper and Bros. issued a small volume of 75 octavo pages on "Röntgen Rays" in which are incorporated memoirs by Röntgen, Stokes, and J. J. Thompson, translated and edited by Dr. Barker.

On the 27th of May, 1893, the American Philosophical Society celebrated the 150th anniversary of its foundation, on which occasion Dr. Barker offered a paper on "Electrical Progress since 1743." This paper is a review of the advances in electricity, since that early date, emphasizing in particular the contributions to electrical science by such persons as the immortal founder of the Society, Benjamin Franklin, and by Kinnersley, Robert Hare, Joseph Henry, Joseph Saxton, David Rittenhouse and Alexander D. Bache. "The labors of these men have mightily contributed to advance the development of scientific thought throughout the world, and so to bring about that exceptional evolution of electrical facts and theories which is the distinguishing feature of the science of the nineteenth century. This little brochure is indeed worthy of study by every student of the physical sciences. It contains an appendix showing a list of ninety-three papers on "Electricity and Magnetism," published by the American Philosophical Society.

Still other communications of Dr. Barker are "On the Henry Draper Memorial Photographs of Stellar Spectra (*Am. Phil. Soc.*, **24**, 166); "On the Use of Carbon Bisulphide in Prisms" (*Am. J. Sci.*, third series, **29**, 269), in which article there is presented to the public the observations of his friend, Dr. Henry Draper, taken from the notes of the latter after his death; and "The Microphone of Hughes" (*Am. J. Sci.*, third series, **16**, 60), in which Dr. Barker takes occasion to say that the results obtained by Hughes had been clearly anticipated by more than a year by those of Edison. His argument, throughout, is in support of Edison's apparatus, and there is frequent demonstration of its superiority over that of Hughes.

Biographical memoirs of Frederick Augustus Genth, of Henry Draper, of John William Draper, and of M. Carey Lea were written for the National Academy by Dr. Barker, and he also prepared for the Smithsonian Institution annual reports upon physics from the year 1881 to 1885, inclusive. These amount to 253 pages and represent the most recent advances in the science during these years.

From 1868–1900 he was Assistant Editor of the *American Journal of Science*. In 1874–75 he was Editor of the *Journal of the Franklin Institute.*

In 1892 appeared his "Physics, Advanced Course" from the press of Henry Holt and Company, which immediately met with a most hearty reception and became a standard among the text-books on this most important subject.

It follows naturally that to one so active in the scientific world, there should be awarded numerous honors. Thus, in 1881, Dr. Barker was United States Commissioner to the Paris Electrical Exhibit, a delegate to the Electrical Congress, and Vice-President of the Jury of Awards, receiving the decoration of Commander of the Legion of Honor in France; in 1884, he was United States Commissioner to the Electrical Exhibit in Philadelphia; and in 1893, a member of the Jury of Awards of the World's Columbian Exposition. He was an active member of the National Academy of Sciences, serving on many of its important committees, and also of the American Association for the Advancement of Science, of which he was Vice-President twice, delivering on one of these occasions an address on "The Molecule and the Atom," a most valuable contribution to theoretical chemistry, and President in 1879. He was a corresponding member of the British Association. He was President of the American Chemical Society (1891), the subject of his presidential address being "The Borderland between Physics and Chemistry." He was secretary and later a vice-president of the American Philosophical Society from 1899 until 1909. He was a member of the Physical Society and of the Deutsche chemische Gesellschaft. In 1899 he became an honorary member of the Royal Institute of Great Britain.

He was the recipient of the following academic honors: Doctor of Science from the University of Pennsylvania in 1898; LL.D. from Allegheny College in 1898; and LL.D. from McGill University in 1900.

He became Emeritus Professor of Physics in the University of Pennsylvania in 1900. He was a member of the Century Club of New York and of the University Club of Washington.

In 1861, Dr. Barker was married to Mary M. Treadway, of New Haven, Conn., who, with three daughters, survives this devoted and loving husband and father.

Dr. Barker was born at Charlestown, Mass., July 14, 1835, and died at Philadelphia upon May 24, 1910.

His was a beautiful life, so full of service to his fellow men and so rich in its achievements, that it will ever remain a most precious memory to his many friends.

EDGAR F. SMITH.

WILLARD GIBBS MEDAL.

Owing to the generosity of Mr. W. A. Converse the Chicago Section has established a Gold Medal known as the Willard Gibbs Medal to be awarded annually according to the following regulations transmitted by A. L. Nehls secretary.

RULES FOR THE AWARD OF THE WILLARD GIBBS MEDAL FOUNDED BY WM. A. CONVERSE.

I. A GOLD MEDAL shall be awarded annually for the best paper or address presented before the Chicago Section of the AMERICAN CHEMICAL SOCIETY, provided it be of sufficient merit. This medal shall be known as the WILLARD GIBBS MEDAL, founded by Wm. A. Converse. The award may be made to any one, *provided* he be a member of the AMERICAN CHEMICAL SOCIETY at the time the paper or address was delivered, and provided it is eligible under the following conditions:

(*a*) The Medal shall be awarded at the November meeting of the Chicago Section for a paper or address delivered before the Section between September 1st of the previous year and July 1st of the year of the award. The first medal shall be awarded in November, 1911.

(*b*) The paper or address shall be complete in itself, shall be presented by the author, and shall not have been read or published previously. To be considered for the award a typewritten copy of the paper or address shall be submitted to the jury, through the Chairman of the Section.

(*c*) It is desired that the paper or address, if suitable, be published in one of the publications of the AMERICAN CHEMICAL SOCIETY.

II. The jury to determine the award of the Medal shall consist of the Chairman of the Chicago Section at the time the award is made, who shall, *ex-officio*, be Chairman of the Jury, and four other members of the Section duly elected by it.

III. The Executive Committee of the Chicago Section shall have the power to decide any question not specifically covered by these rules.

IV. The Chicago Section shall have the power to change or amend these rules under the same conditions and in the same manner as the by-laws of the Section.

Issued with the November Number, 1910.

Proceedings.

DIVISION OF AGRICULTURAL AND FOOD CHEMISTRY.

Mr. H. E. Barnard, Food and Drug Commissioner and State Chemist of Indiana, has been elected by the Executive Committee to fill out the unexpired term of Chairman C. D. Woods, resigned.

B. E. Curry, *Secretary.*

COUNCIL.

Members Elected between September 15th and October 15th, 1910.

Ashley, Myron B., Mancelona, Mich.
Avon, Hans, Philippine Medical School, Manila, P. I.
Barbey, Jacob W., 1180 Jos. Campan Ave., Detroit, Mich.
Burleson, H. L., Belvedere, Calif.
Chase, A. Nelson, Barksdale, Wis.
Gaff, Thomas T., 1520 20th St., Washington, D. C.
Gardner, Daniel, Institute of Emperor Nicholas I, St. Petersburg, Russia.
Grab, Eugene G., Custom House, Nashville, Tenn.
Hawkes, Frank E., So. Framingham, Mass.
Hogg, Elton M., Saratoga, Calif.
Higgins, Wilton A., Shawinigan Falls, Que., Canada.
Holden, R. F., 2322 So. Compton Ave., St. Louis, Mo.
Jacobs, Paul Burke, Thomas, W. Virginia.
James Pyle & Sons, Edgewater, N. J.
Johnson, Harold S., 3359 Wabash Ave., Chicago, Ill.
Loomis, Howard, Brookings, So. Dakota.
Malowan, G., 515 North Clark St., Chicago, Ill.
Moe, J. A., 528 E. Clay St., Portland, O.
Morris, Clinton, Goodrich, Tenn.
Neff, Byron D., Indianapolis, Ind.
Noble, Edward W., Winston-Salem, No. Car.
Peterson, Andrew P., 1728 4th St., S. E., Minneapolis, Minn.
Pullar, H. B., 7323 Woodlawn Ave., Chicago, Ill.
Robinson, Samuel R., 1055 Dillon Ave., Coraopolis, Pa.
Rogers, L. Joslyn, 381 College St., Toronto, Ont., Canada.
Stacy, E. E., Tuscola, Ill.
Sydnor, Leslie W., Carbon, West Virginia.
Terry, Ethel M., 6042 Engleside Ave., Chicago, Ill.
Traut, Carl E., 86 Cherry St., Battle Creek, Mich.
Tritsch, Dr. Walter, c/o Tungsten Lamp Co., Hamilton, Ont., Canada.
Weaver, Elmer R., Raisin, Calif.
Whittaker, H. A., Lab'y Minn. State Board of Health, Minneapolis, Minn.

BOARD OF DIRECTORS.

The Directors of the American Chemical Society met at 3.00 P.M., October 8th, at the Chemists' Club, New York City. All members present.

It was voted that beginning with the January number, 1911, of the *Journal of Industrial and Engineering Chemistry*, the body of the journal be printed in nine (9) point type, and that notes, patents, etc., in the end of the *Journal* be continued in eight (8) point type as heretofore.

It was voted to transfer $550.00 from General Meetings' account, and credit $400.00 to back number account and $150.00 to Secretary's expense account.

Mr. Harvey F. Mack was appointed advertising agent for the journals of the Society, and the officers of the Society were authorized to sign a contract with him, details of which were carefully considered and approved by the Directors.

It was voted that the existing rates of advertisements be approved, and that the advertising agent be allowed to give 10 per cent. discount to publishers who advertise in our journals and 2 per cent. to any advertiser for cash.

It was voted that hereafter free advertisements allowed to members seeking employment be limited to ¾ in. space and two insertions, and that extra space or extra insertions be paid for at regular advertising rates.

It was voted that $400.00 additional be appropriated to Abstractors' account of *Chemical Abstracts*.

The meeting then adjourned.

CHARLES L. PARSONS, *Secretary*.

MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons, Durham, N. H.]

CHICAGO SECTION.

The September meeting was held at the City Club, Friday, September 23rd.

The program for the evening was "Milk:" (1) "Toxicity of Milk and Milk Serum," Dr. Edward Gudeman; (2) "Cost of Production of Milk," J. P. Grier, Secretary Chicago Milk Producers' Association; (3) "Cost of Distribution of Milk," Dr. H. R. Ryder, Borden's Condensed Milk Co.; (4) "Condition of the Chicago Milk Supply," D. T. Gunning, Assistant State Chemist.

The discussion was led by J. B. Newman, Assistant State Food and Dairy Commissioner.

Members of the Section held the usual informal dinner before the meeting.

A. L. NEHLS, *Secretary*.

SECTION OF EASTERN NEW YORK.

The September meeting was held in the Union College Chemical Lecture Room, Friday evening, Sept. 23rd, at 8 o'clock. The following program was presented:

I. A. R. I. 75.

IMPERIAL AGRICULTURAL RESEARCH
INSTITUTE LIBRARY
NEW DELHI.
